Background

- Each year, nearly one-third of adults aged 65 years and older have an unexpected fall resulting in disability, decreased independence, and reduced quality of life.
- Evidence suggests that exercise programs which specifically challenge balance are the most effective at preventing falls.
- Participation in yoga as an alternative intervention strategy has become an emerging trend.
- Yoga has been shown to improve balance, prevent falls, and reduce the fear of falling in the older adult population.
- Although there has been growing interest in yoga as an alternative therapy for improving balance and reducing fall risk in the older adult population, more research is needed to specifically link yoga to a reduction in fall risk.

Purpose & Hypothesis

The purpose of this systematic review was to determine the effects of a regular yoga program on balance in older adults. We hypothesized that a regular yoga program would improve balance and consequently reduce fall risk in the older adult population.

Methods

Review protocol
- Based on Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) guidelines

Search terms
- Yoga
- Older adults
- Balance

Grading the evidence
- Sackett Scale
- Consultation between all four researchers and the faculty advisor to resolve discrepancies
- Risk of bias include lack of blinding and self-reporting measures

Discussion

Key points
- Yoga programs can be used to improve balance in older adults
- Participation in yoga programs led to improvements in quality of life, functional strength, and performance of ADLs.

Why did yoga improve balance?
- EMG studies showed poses such as down dog, plank, chair and mountain with arms up engage key trunk musculature which assist with balance and ADL performance.
- Yoga has been shown to increase body awareness, which contributes to improved balance in older adults.

Fear of falling
- Fear of falling efficacy scale scores improved in three of the studies. However FOF remained in the majority of participants.
- We hypothesize that yoga programs that are longer in duration may be needed to improve FOF, especially in those who have experienced a fall in the past.

Clinical Relevance

Evidence shows
- Exercise programs that include endurance, balance, and strengthening components are recommended to reduce fall risk.
- Yoga programs can improve balance in older adults, which can reduce risk of falling.

How clinicians can use the results
- Incorporate yoga poses in their treatment plans.
- Educate patients on how to utilize local yoga programs to maintain and improve balance once formal physical therapy treatment is completed.
- Clinician should only recommend yoga programs that are safe and appropriate for the older adult population.

Future Research

Yoga is an emerging alternative therapy which has been proven to have several physiological benefits. Future research is recommended in order to determine the following:
- Appropriate duration and length of a yoga program to achieve significant improvements on balance measures
- Effects of sound versus standing yoga on balance in the older adult population
- Effects of balance on a novice yoga practitioner compared to an expert practitioner
- Impact of yoga on strength, flexibility, cardiovascular and pulmonary health, mental health, and neurological conditions (e.g. multiple sclerosis, Alzheimer’s, Parkinson’s)
