Barefoot running may reduce incidence of injury as a result of a change in foot strike pattern. Understanding the foot strike, it has been found that certain foot strike patterns are more susceptible to injuries, such as patellar tendinitis (PFPS), plantar fasciitis, and metatarsal stress fractures. Conversely, runners demonstrating a forefoot strike (FFS) pattern (defined as the ball of the foot usually the 4th and 5th metatarsal heads-landing before the heel) are more susceptible to Achilles tendon, plantar fascia, and metatarsal injuries. Several systematic studies have concluded that barefoot runners employed a FFS pattern while shod runners used a RFS pattern. The purpose of this systematic review was to determine the effects of transitioning from traditionally shod running to barefoot running on self-selected contact patterns in long-distance runners.

METHODS

Searches databases: Ovid, PubMed, SCOPUS, CINAHL, The Cochrane Library, Google Scholar

Search Terms: Barefoot, Shod, Minimalist, Transition, Pattern, and Initial Contact

Articles were eliminated by title, abstract, and then by content. The final 11 articles were read in full and graded using the PEDro scale.

CLINICAL RELEVANCE

- Barefoot running may reduce incidence of injury as a result of a change in foot strike pattern.
- None of the 11 studies supported a self-selected change in foot-strike with barefoot running.
- Foot-strike motor patterns developed over years of running may prevent acute changes in foot-strike pattern when transitioning between shod and barefoot.
- It would be good clinical decision making for physical therapists to include education on proper foot feel when transitioning from shod to barefoot.
- There is currently no standard protocol for transitioning from shod to barefoot running.
- Adapting to barefoot running should occur gradually in order to allow the body to acclimate to the newly imposed biomechanical stresses.
- Understanding the natural tendency to change to a MPS or FFS pattern following transition to barefoot can be useful in guiding physical therapy diagnoses and interventions.

CONCLUSION

The literature supported that a runner’s initial contact changed from a RFS pattern to a more anterior foot-strike pattern when transitioning from habitually running shod to running barefoot. Future studies should focus on the incidence of injury while transitioning acutely or gradually from shod to barefoot running. This will help determine if a transition protocol is necessary for a runner to safely acclimate between shod and barefoot.
