Introduction

Cervicogenic headache describes pain referred to the head from a source in the cervical spine. The diagnosis of this disorder is controversial. Some authorities believe that clinical criteria alone are sufficient while others, including the International Headache Society, require confirmatory tests to establish the diagnosis. A multidisciplinary approach is often required to adequately manage this disorder. The purpose of the current review is to provide an overview of the diagnosis and treatment of cervicogenic headache. Further discussion focuses on associated disorders including whiplash, a common cause of cervicogenic headache.

Cervicogenic Headaches

Neck pain and tenderness are common symptoms present in many headache disorders. When cervical dysfunction or degenerative changes cause headache it is referred to as cervicogenic headache. Cervicogenic headache prevalence is estimated at 0.5%-4%, but may be as high as 20% of patients presenting with severe chronic headaches. The mean age of patients with this condition is 43 years; the condition is more common in women.

The International Headache Society defines diagnostic criteria for cervicogenic headache (Table 1). The most useful clinical features are pain that radiates from the neck to the frontotemporal region and pain that is reproduced with neck movements. The diagnostic criteria may help distinguish between cervicogenic headache and migraine symptoms, especially when a history of neck trauma is present.

The most common source of cervicogenic headache is degenerative changes involving the upper cervical facet joints. While diagnostic imaging with magnetic resonance imaging (MRI), and computed tomography (CT) myelography can help support the diagnosis of cervicogenic headache, these radiographic studies are probably more useful in ruling out secondary causes of pain. Controlled diagnostic facet blocks using fluoroscopic guidance is one means to confirm the diagnosis of cervicogenic headache and possibly predict response to treatment modalities.

There is no proven cure for cervicogenic headache. A comprehensive, multidisciplinary pain treatment program provides the greatest opportunity for overall clinical improvement. Pharmacologic treatments for chronic cervicogenic headache include medications that are used for the prevention or palliative management of neuropathic pain, such as tricyclic antidepressants, anticonvulsants, or other analgesics. Physical therapy may provide long-term improvement with a combination of manipulative and exercise therapy. Percutaneous radiofrequency neurotomy can be considered if diagnostic blockade is temporarily successful in providing complete pain relief. Lastly, there are reports of reduced headache frequency and intensity after surgical implantation of occipital or spinal nerve stimulators.

Whiplash

The term whiplash describes a constellation of symptoms and signs associated with bony or soft tissue injury occurring most commonly after a motor vehicle accident. The Quebec Task Force (QTF) of whiplash associated disorders developed a classification system based on severity of signs and symptoms (Table...
2) In their critical review of the literature, the Neck Pain Task Force (NPTF) proposed that the QTF grading system be adapted to classify neck pain of any etiology including non-traumatic cervicalgia. Whiplash remains a common cause of disability and is the most common injury associated with motor vehicle accidents, affecting up to 83% of victims.

Current theories of the etiology of whiplash suggest that it occurs as a result of hyperextension of the lower cervical vertebrae in relation to a relative flexion of the upper cervical vertebrae. This type of abnormal motion may result from an acceleration-deceleration energy transfer to the spine that is typical of forces experienced by restrained passengers in motor vehicles that are ‘rear-ended’.

Headaches may be present in 30 to 75% of acute whiplash sufferers. Although the methodology of studies in this area make interpretation difficult, cervicogenic headaches appear to comprise a significant proportion of post-whiplash headache syndromes. Treatment for whiplash in the absence of other pathology is primarily focused on physical therapy, self-mobilization, and return to normal activities as soon as possible. Recent studies suggest that early mobilization may lead to improved outcomes and that early motion restriction may have the opposite effect. Treatment of whiplash injuries often presents a challenge to the clinician because of the complex interaction of psychosocial, physical, and legal factors amongst different patients.

### Differential Diagnoses

The multiple possible causes of suspected cervicogenic headache encompass a number of diseases requiring medical and/or surgical treatment. Chiari malformations, posterior fossa tumors, and vertebral or internal carotid artery dissections may all present with similar signs and symptoms as cervicogenic headache. Cervical spondylosis, herniated cervical intervertebral discs, spinal nerve compression, migraine and cluster headaches, and hemicrania continua are less serious causes of neck and head pain. A detailed history and physical by the informed clinician as well as proper imaging studies, when appropriate, can help to confirm or reject alternative diagnoses.

Chiari malformation is a downward displacement of the cerebellar vermis and tonsils through the foramen magnum. The brainstem, cranial nerves, and cerebellum may be compressed and symptoms related to the compression are common. Headaches may also occur in these patients. Chiari-associated headaches are classically protracted, suboccipital-occipital headaches of variable duration that are aggravated by Valsalva maneuvers, cough, or postural changes. The headaches may be relieved with suboccipital decompression, although observational therapy is also often appropriate. Migraine and tension-type headaches occur in these patients as well but at a rate equal to the general population.

Occipital neuralgia (Arnold’s neuralgia) is paroxysmal pain in the distribution of the greater or lesser occipital nerves. It may be associated with dysesthesia, hypesthesia, or tenderness in the affected area. It may be caused by muscle tension, muscle spasm, migraine headaches, or cranio-cervical junction disease. The pain may be unilateral or bilateral in distribution and the diagnosis can be confirmed by relief with local anesthetic block of the involved nerve.

### Conclusion

Though the pathogenesis of cervicogenic headaches is relatively straightforward this disease presents several challenges to the practicing clinician. Even with established guidelines for diagnosis from several prominent specialty committees there is still some controversy on this topic. Although cervicogenic headache is a relatively common cause of chronic headache it is often misdiagnosed or unrecognized. Its differential is broad and includes diseases that can cause significant pathology if not diagnosed in a timely fashion. This requires the examiner to remain attentive to details in the history and physical and obtain appropriate imaging when necessary. With early diagnosis and management, physicians can help their patients significantly decrease the potential pain and disability associated with this challenging disorder.
