Abstract

Objective. To investigate the role of Junctional adhesion molecule A (JAM-A) in the pathogenesis of systemic sclerosis (SSc).

Methods. Biopsies from proximal and distal arm skin and serum were obtained from patients with SSc and normal (NL) volunteers. To determine the expression of JAM-A on SSc dermal fibroblasts and in SSc skin, cell surface ELISAs and immunohistology were performed. An ELISA was designed to determine the amount of soluble JAM-A (sJAM-A) in serum. Myeloid U937 cell-SSc dermal fibroblast and skin adhesion assays were performed to determine the role of JAM-A in myeloid cell adhesion.

Results. The stratum granulosum and dermal endothelial cells (ECs) from distal arm SSc skin exhibited significantly decreased expression of JAM-A compared to NL. However, sJAM-A was elevated in the serum of patients with SSc compared to NL. Conversely, JAM-A was increased on the surface of SSc compared to NL dermal fibroblasts. JAM-A accounted for a significant portion of U937 binding to SSc dermal fibroblasts. In addition, JAM-A contributed to U937 adhesion to both distal and proximal SSc skin.

Conclusions. JAM-A expression is dysregulated in SSc skin. Decreased expression of JAM-A on SSc ECs may result in a reduced response to proangiogenic basic fibroblast growth factor. While increased JAM-A expression on SSc fibroblasts may serve to retain myeloid cells, which in turn secrete angiogenic factors.

The pathogenesis of systemic sclerosis (SSc) is complex and remains incompletely understood, however fibroblasts, monocytes, and endothelial cells (ECs) seem to be key players. These cells facilitate excessive synthesis of extracellular matrix proteins and deposition of increased amounts of collagen, immune activation, and vascular damage, all of which are known to be important in the development of this illness.[1]

Adhesion molecules play multiple roles in angiogenesis. Specific adhesion molecule expression can mediate angiogenesis indirectly by promoting the migration of monocytes.[2] These monocytes are then capable of becoming tissue macrophages and secreting angiogenic factors. Cellular adhesion molecules may have a role in the immunopathogenesis of SSc.[3] We and others have shown that several adhesion molecules are overexpressed in SSc skin.[4, 5] A number of soluble adhesion molecules are also elevated in SSc.[3]

JAM-A has been implicated in a variety of physiologic and pathologic processes involving cellular adhesion, tight junction assembly, and leukocyte transmigration.[6, 7] JAM-A facilitates leukocyte adhesion and transmigration through its interaction with lymphocyte function-associated antigen 1 (LFA-1). Recently, JAM-A has been shown to play a role in angiogenesis.[8]

As SSc is characterized by both inflammatory cell infiltration and vasculopathy, we hypothesized that JAM-A may play a role in its pathogenesis. Here we demonstrate aberrant expression of JAM-A in SSc skin and sJAM-A in SSc serum. Moreover, we show a novel role for JAM-A in mediating myeloid cell adhesion to SSc skin.

Materials and methods

Patients and controls. Skin punch biopsies and peripheral blood samples were obtained from subjects with SSc (all with diffuse disease) and control subjects. All SSc patients fulfilled the American College of Rheumatology criteria for SSc and also met the criteria for diffuse SSc.[1, 9] Biopsies were taken with full informed consent, and this study was approved by the Institutional Review Board.

Immunohistology. We performed immunohistologic staining on cryosections from SSc and normal skin, as described previously.[10] Goat anti-human JAM-A antibody (R&D Systems, Minneapolis, MN) was used as a primary antibody. The slides were read by a pathologist under blinded conditions. For JAM-A staining, the percentage of positive cells was calculated semi-quantitatively as stained cells in proportion to all cells of a distinctive subset. We also used a similar method with an anti-von Willebrand factor antibody to identify endothelial cells. Blood vessels were scored using a scale of: 0=avascular; 1=slight decrease; 2=normal; 3=slight increase; 4=marked increase.

Immunofluorescence. We performed immunofluorescence on cryosections from SSc and normal skin. Sections were fixed with 4% formalin and blocked with 20% fetal bovine serum and 5% donkey serum. Goat anti-human JAM-A antibody (R&D Systems) and mouse anti-human Von Willebrand factor (vWF) (Dako, Denmark) were used as primary antibodies. Fluorescent conjugated secondary antibodies were purchased from Molecular Probes (Eugene, OR). 4',6-diamidino-2-phenylindole (DAPI) was used to stain cell nuclei. Images were taken at 400x.

Cell lysis and western blotting. NL and SSc dermal fibroblast cell lines were established as described previously.[11] Cell lysis and western blotting were performed as described.[10] Membranes were probed with anti-human JAM-A antibody (R&D Systems). Densitometric analysis of the bands was performed using UN-SCAN-IT software, version 5.1 (Silk Scientific).

Cell surface ELISA. Cell surface ELISAs were performed as previously described.[10] Dermal fibroblasts were plated in 96-well plates, stimulated with tumor necrosis factor-alpha (TNF- α), or interleukin-1 β (IL-1 β), or interferon- γ (IFN- γ) (all 25 ng/ml, R&D Systems) or incubated in serum free RPMI for 24 hours. The fibroblasts were incubated with anti-human JAM-A antibody (R&D Systems) or goat IgG.

Human dermal microvascular endothelial cell (HMVEC) cell culture. HMVECs were obtained from Lonza (Basel, Switzerland) and cultured using EBM complete media (Lonza). The cells were serum starved overnight and then stimulated with either TNF- α or IL-1 β . Supernatants were collected and concentrated using Amicon ultra filters (Millipore).

Serum JAM-A ELISA. Ninety six well microplates were coated with anti-human JAM-A antibody (R&D Systems) and blocked with 1% bovine serum albumin in PBS. Sample or standards (R&D Systems) was added, followed by the addition of mouse anti-human JAM-A antibody (Santa Cruz, Santa Cruz, CA), anti-mouse biotinylated antibody (Vector Laboratories), streptavidin-HRP (R&D Systems), TMB substrate solution, and 2N H₂SO₄. The absorbance of each well read using a microplate reader at 450/570 nm. The detection limit of the sJAM-A ELISA was 0.3 ng/ml.

U937 cell-fibroblast adhesion assay. Adhesion assays were performed as previously described using myeloid U937 cells.[10] These cells are human histiocytic lymphoma cells that are myeloid. Combinations of JAM-A neutralizing antibody (Santa Cruz), mouse antibody to human

CD11a (GeneTex Incorporated), neutralizing mouse anti-human ICAM-1 antibody (R&D Systems), or mouse IgG were used. The inhibitory effect of neutralizing antibody treatment was given as the percentage of maximal binding, which was defined as the number of adherent cells in the control antibody treated sections.

Stamper-Woodruff adhesion assay. *In situ* assays were performed as previously described.[10] JAM-A neutralizing antibody (R&D Systems) or goat IgG control were added to the skin sections. U937 cells were labeled with Calcein-AM fluorescent dye (5 μ M, Invitrogen) and added to the sections and incubated for 1 hour in the dark. Non-adherent cells were washed off. The total number of fluorescence-labeled U937 cells was counted by a blinded observer using a fluorescence microscope. The inhibitory effect of the anti-JAM-A antibody was given as the percentage of maximal binding, which was defined as the number of adherent cells in the control antibody treated sections.

Statistical analysis. Student's t-tests were performed, and P values less than 0.05 were considered significant. All values presented were the mean \pm standard error of the mean (SEM).

Results

Patient characteristics. The SSc group consisted of 18 females and 2 males (52.5 ± 1.8 years), while the NL control group consisted of 7 males and 3 females (51.2 ± 4.4 years). The mean disease duration of the SSc group was 3.7 ± 0.8 years. Punch biopsies were taken from clinically less involved proximal arm skin (mean skin score 1.2 ± 0.2) and involved distal forearm skin (2.0 ± 0.2). The proximal biopsy site was far away from the leading edge of the distal area.

SSc distal arm skin had significantly fewer blood vessels compared to NL skin. Our work confirmed that in our patient population SSc distal arm skin has significantly fewer blood vessels (blood vessel score=1.7) compared to NL skin (blood vessel score=2.0, $p<0.05$) (figure 1).[12] In addition, we found that SSc proximal arm skin (blood vessel scale score=1.9) had a blood vessel score between that of SSc distal skin and NL skin.

JAM-A is abnormally expressed in SSc skin. JAM-A expression in normal and SSc skin was evaluated using immunohistology and immunofluorescence. JAM-A is expressed on dermal ECs, fibroblasts, macrophages, and in the epidermis (figure 2). Moreover, dual immunofluorescence using anti-JAM-A and anti-vWF antibodies further indicated that JAM-A is expressed on dermal ECs. As shown in figure 2I, quantification of JAM-A immunohistology demonstrated that SSc dermal ECs exhibited significantly decreased expression of JAM-A (mean of 71%) compared to NL controls (mean of 93%, $p<0.05$). In addition, JAM-A was less expressed in the stratum granulosum of the epidermis of distal SSc skin (mean of 50%) compared to NL skin (mean of 98%, $p<0.05$, figure 2J). In contrast, SSc dermal perivascular macrophages expressed increased levels of JAM-A (12% in distal skin and 18% in proximal skin) compared to NL skin (mean of 4%, both $p<0.05$) (data not shown). Similarly, SSc

subepidermal macrophages expressed increased levels of JAM-A (mean of 8% in distal skin and mean of 8% in proximal skin) compared to NL skin (mean of 3%, both $p < 0.05$) (data not shown).

JAM-A was more highly expressed on SSc dermal fibroblasts vs. NL dermal fibroblasts.

JAM-A was more highly expressed on dermal SSc compared to NL fibroblasts (figure 3A). Western blotting resulted in similar results (figure 3B). However, the expression of JAM-A on either SSc or NL dermal fibroblasts was not inducible by TNF- α , IFN- γ , or IL-1 β (data not shown).

Elevated sJAM-A in SSc serum. A sJAM-A ELISA was designed, and serum JAM-A was detected in all normal volunteers and SSc patients. The concentration of sJAM-A in the serum of patients with SSc was 2.4 ± 0.4 ng/ml, whereas the concentration for NL controls was 1.0 ± 0.2 ng/ml ($p < 0.05$) (figure 4).

sJAM-A is secreted by ECs. sJAM-A was detectable in the culture supernatant of HMVECs. Moreover, stimulation with TNF- α resulted in a significant increase of sJAM-A in HMVEC culture supernatants.

JAM-A mediates myeloid U937 cell binding to SSc dermal fibroblasts. We found that SSc dermal fibroblasts bound a greater number of myeloid U937 cells than NL dermal fibroblasts ($p < 0.05$) (data not shown). Moreover, JAM-A accounted for a significant portion of U937 binding to SSc dermal fibroblasts. U937 binding to SSc dermal fibroblasts was inhibited by neutralizing anti-JAM-A antibody treatment (86% of maximal binding, $p < 0.05$) (figure 5). Neutralizing antibody against the JAM-A ligand LFA-1 also inhibited U937 cell binding to SSc dermal fibroblasts (90% of maximal binding, $p < 0.05$). Similarly, neutralizing antibody against the LFA-1 receptor ICAM-1 inhibited U937 cell binding to SSc dermal fibroblasts (83% of maximal binding). A combination of neutralizing antibodies against JAM-A, LFA-1, and

ICAM-1 resulted in the greatest inhibition of U937 cell binding to SSc dermal fibroblasts (73% of maximal binding).

JAM-A contributes to U937 cell adhesion to SSc skin. We found that similar to the results of the U937-fibroblast *in vitro* adhesion assay, anti-JAM-A neutralizing antibody decreased U937 cell binding to SSc skin (figure 6). U937 cell binding to SSc proximal arm skin (44% of maximal binding, $p<0.05$) and distal forearm skin (61% of maximal binding, $p<0.05$) was inhibited by anti-JAM-A antibody treatment. Collectively these results indicate that JAM-A plays an important role in myeloid cell adhesion to SSc skin.

Discussion

The etiology and pathogenesis of SSc remains unknown. Nonetheless, signs of vascular injury and devascularization of involved organs in association with evidence of profound endothelial dysfunction are well documented. Adhesion molecules, molecules known to promote both inflammatory cell infiltration and angiogenesis, may play a role in the pathogenesis of SSc.[3]

Our results demonstrated that dermal ECs from SSc skin exhibit decreased expression of JAM-A compared to ECs in NL skin. Decreased JAM-A expression increases permeability. Blocking JAM-A expression caused a decrease in neutrophil and monocyte extravasation in several models including inflammatory meningitis, peritonitis, and ischemia-reperfusion injury.[13-16] These findings suggest that the downregulation of JAM-A expression on SSc dermal ECs may effect the influx of leukocytes into SSc skin.

In addition, JAM-A is a proangiogenic adhesion molecule. JAM-A forms a complex with integrin $\alpha_v\beta_3$ and mediates basic fibroblast growth factor (bFGF) induced angiogenesis.[8] JAM-A overexpression on ECs induces both EC proliferation and migration on vitronectin. In addition, inhibition of JAM-A signaling blocks bFGF-induced EC proliferation, tube formation and *in vivo* angiogenesis.[8, 17] Our results demonstrate that JAM-A is downregulated on SSc dermal ECs, and therefore may not be able to respond to bFGF and mediate angiogenesis.

Soluble adhesion molecules have also been shown to be elevated in patients with SSc. Recently, Cavusoglu et al. observed significantly higher levels of plasma sJAM-A in patients with advanced coronary artery disease and indicated that JAM-A may be an important mediator of the effects of inflammation on the vessel wall.[18] Our results show that the concentration of sJAM-A in the serum of patients with SSc is elevated compared to NL serum. Moreover, we

demonstrated that sJAM-A can be secreted by cultured ECs. This is the first study to suggest a link between serum sJAM-A concentration and SSc, and further study is needed to determine if the concentration of serum sJAM-A correlates with additional clinical manifestations of SSc.

Previous studies have shown that SSc peripheral blood mononuclear cells (PBMCs) and SSc dermal fibroblasts are hyperadhesive.[19] Here we found that JAM-A is overexpressed on SSc dermal fibroblasts and mediates the adhesion of myeloid U937 cells to both SSc dermal fibroblasts and proximal and distal SSc skin. As myeloid cells mature into monocytes and macrophages that have the potential to secrete a variety of angiogenic factors, our results have particular importance to the pathogenesis of SSc.

Our study suggests that JAM-A plays multiple roles in the pathogenesis of SSc. The reduced expression of JAM-A on the surface of ECs may contribute to dysregulated angiogenesis in SSc skin, as JAM-A EC expression is required for bFGF induced angiogenesis.[8, 20, 21] Moreover, the elevated SSc serum levels of sJAM-A could be the result of the characteristic EC injury in SSc, further strengthening the suggestion of JAM-A as a vascular disease marker.[18] In contrast, JAM-A exemplifies the dual nature of an adhesion molecule, as our results demonstrate its importance in mediating myeloid cell retention in SSc skin. Collectively, these results suggest that JAM-A is dysregulated on multiple cell types in SSc, and that further study on its role in SSc skin angiogenesis is warranted.
