Utilization of care by infants with neonatal abstinence syndrome in Delaware

Michele K Savin, DNP, APRN, NNP-BC

Christiana Care Health System

Abstract

There is little information regarding use of expected well care by infants diagnosed with neonatal abstinence syndrome (NAS) post initial discharge. Via a de-identified State of Delaware Medicaid data set, claims for inpatient and outpatient care were extracted for one year after birth and were examined regarding utilization rates for primary care, vaccination, urgent or emergency care, and re-hospitalization.

Key findings include less than expected well-child visits and immunizations along with higher hospital re-admission rates. This represents missed opportunities for care, also demonstrating the need for more robust social support. Potential for prospective outpatient management and avenues for future research are outlined.

Purpose

1) Identify health system utilization after discharge for infants with a diagnosis of NAS
2) Identify points of interaction with the system of care
3) Quantify routine and non-routine health care interactions
4) Recognize existing gaps in care and recommend changes for improved provision of care

Demographics

![Graph showing demographics](image)

There are 522 babies in the full data set, which represent all infants born in Delaware January 1, 2012 through December 31, 2014 who received a diagnosis of NAS at birth and were insured by Medicaid.

Four infants without inpatient or discharge codes were excluded from the analysis. This left 518 infants whose initial length of stay (LOS) could be ascertained. Fifteen percent (n=79) had a diagnosis of prematurity. The total number of infants and lengths of stay increased over time for all demographics. Twenty percent (n=103) of infants had LOS < 5 days. This may represent exposure rather than withdrawal.

Mean Length of Stay for Infants with NAS

</tr>
</tbody>
</table>

Expected Utilization of Care

- Nineteen infants without codes after discharge were excluded from the analysis. These infants were likely moved to another form of insurance or re-located out of state. The final n=499.
- Any well-child visit within two weeks before or after the recommended age was considered to meet the AAP well-child requirement.
- Immunization coding did not allow for delineation of which vaccine was received, therefore information is presented in aggregate.

Well Child Adherence

</tbody>
</table>

Immunizations

- Children received immunizations at both well visits and visits to the primary care office for other reasons.
- The total number of infants who received any immunization in the first year of life was 459, or 92% which is inclusive of immunizations received during the birth hospitalization.
- The mean number of immunizations received per child was 12.6 with a standard deviation of 6.6.
- Eight percent (n=40) never received any immunization.
- Fifty-eight percent (n=23) of those not receiving immunizations were Caucasian and 42 percent (n=17) were Black/Asian/Hispanic.
- Of these 40 infants, only 33 had a well visit, 35 had a primary care visit, and 16 visited the emergency room.
- This lack of immunization is higher than the baseline US rate of one percent (CDC, 2014) and represents a lost opportunity for well-child care.

Unexpected Utilization of Care

- Fifty-two percent (n=261) had a visit to the Emergency Department during the first year of life. The mean number of visits per child was 2.1 with a standard deviation of 1.5.
- Seven percent (n=33) visited an urgent care clinic.
- Fifteen percent (n=74) of infants needed hospitalization in the first year of life which is higher than the baseline for term infants of 9.5%.
- Of those infants admitted, 78% (n=58) had one admission, and 22% (n=16) had two or three admissions.

Primary Reasons for Utilization of Care at Differing Sites

<td>Failure to thrive</td>
<td>Other unspecified morbidity and mortality</td>
<td>Outpatient</td>
</tr>
</tbody>
</table>

Conclusions

- Ninety-seven percent of children had some form of well-child or primary care visit. Over time the rate of attendance at a well-child visit dropped to only 30%.
- Eight percent of NAS infants studied never received any vaccinations, compared with a recent national average of less than one percent.
- The baseline hospitalization rate for term infants in the first 365 days of life is 9.3% in this cohort, 15% required admission with 22% of those infants requiring more than one admission. Visits to the emergency department for head trauma and other morbidity and mortality were noted.
- Lack of attendance at well-child visits means a loss of preemptive well care, developmental screening and early intervention.
- Full engagement in primary care may also decrease the need for urgent and emergency room care.
- Findings of this nature present an opportunity for education and demonstrate the need for social supports to enable safe environments.
- Future research should include real-time and prospective analysis of healthcare utilization with a case management focus, research to examine changes in utilization of urgent care, to inform plans of safe care, and research into how to best support the substance exposed mother-infant dyad and their families.
