What’s the Problem?

COVID-19 patients are at risk for becoming quickly deconditioned, especially in the hospital setting given the nature of the virus and those that get admitted. The concern for deconditioning stems from patients being confined to their room, the need to minimize exposure amongst healthcare providers and the need to conserve PPE. We wanted to find ways to optimize opportunities for patient mobility, maintain patient and provider safety, all while conserving PPE. We reviewed the Chinese Association of Rehabilitation Medicine guidelines to help develop the exercise program.

How Might We: Improve mobility of patients with COVID-19 to minimize deconditioning, improve quality of life and decrease LOS.

We developed a standardized supine, seated and standing exercise program with handouts and videos that complemented each. Handouts were created using VHI computer software and provided to RN managers and therapy staff. Videos were loaded onto Jefferson Health YouTube for patients to access on IPads in the room and upon d/c home.

Cause analysis

Root causes of this problem included:
- Evolving understanding of ideal time to initiate PT and/or OT for patients with COVID-19.
- Differences in provider comfort to mobilize patients.
- Lack of established standardized exercise programs that could be shared with patients by any provider.
- Evolving understanding of appropriate PT and/or OT consults pre-COVID-19 and during COVID-19.
- Lack of common language for patients’ mobility status.

We also developed a step by step video on how to mobilize a patient requiring minimal assist from supine to sitting EOB to standing and then back to supine. The video was shared with nursing and housestaff and placed on MYJeffHub as a resource.
