RESEARCH ARTICLE

Neural crest cell-autonomous roles of fibronectin in cardiovascular development

Xia Wang and Sophie Astrof*

ABSTRACT

The chemical and mechanical properties of extracellular matrices (ECMs) modulate diverse aspects of cellular fates; however, how regional heterogeneity in ECM composition regulates developmental programs is not well understood. We discovered that fibronectin 1 (*Fn1*) is expressed in strikingly non-uniform patterns during mouse development, suggesting that regionalized synthesis of the ECM plays cell-specific regulatory roles during embryogenesis. To test this hypothesis, we ablated *Fn1* in the neural crest (NC), a population of multi-potent progenitors expressing high levels of *Fn1*. We found that *Fn1* synthesized by the NC mediated morphogenesis of the aortic arch artery and differentiation of NC cells into vascular smooth muscle cells (VSMCs) by regulating Notch signaling. We show that NC *Fn1* signals in an NC cell-autonomous manner through integrin $\alpha 5 \beta 1$ expressed by the NC, leading to activation of Notch and differentiation of VSMCs. Our data demonstrate an essential role of the localized synthesis of *Fn1* in cardiovascular development and spatial regulation of Notch signaling.

INTRODUCTION

Aortic arch arteries (AAAs) route oxygenated blood from the heart to the rest of the body. Malformations in this vascular tree are common causes of morbidity and mortality in patients with congenital heart disease (CHD) (Go et al., 2013; Moon, 2008, 2006). Development of the AAAs occurs similarly in humans and in mice, and results from asymmetrical remodeling of the three pairs of pharyngeal arch arteries (PAAs) that are initially positioned symmetrically around the midline (Conway et al., 2003; Stoller and Epstein, 2005) (Fig. 1A,B). Animal models indicate that defective remodeling of initially well-formed, symmetrical PAAs may cause some forms of CHD, e.g. the Alagille syndrome (High and Epstein, 2008). In this syndrome, as well as in many non-syndromic CHD patients, the AAA abnormalities stem, in part, from defects in derivatives of the 4th pair of PAAs (the left and/or the right). The left 4th PAA gives rise to the aortic arch and the right 4th PAA gives rise to the proximal segment of the right subclavian artery (Stoller and Epstein, 2005). Regression of the left 4th PAA results in the interrupted aortic arch, which is lethal. Regression of the right 4th PAA results in a vascular abnormality called retroesophageal right subclavian artery (RERSA), in which the

right subclavian artery originates from the descending aorta on the left, instead of the brachiocephalic trunk on the right (Stoller and Epstein, 2005).

The development of vascular smooth muscle cells (VSMCs) around the three symmetrical pairs of PAAs is necessary to prevent premature regression of these vessels and to facilitate their asymmetrical remodeling (High et al., 2007; Hutson and Kirby, 2007; Yashiro et al., 2007). VSMCs surrounding the PAA endothelium derive from the neural crest (NC) – a population of neuroectodermal stem cells that originate along the anterior–posterior axis at the dorsal margin of the neural tube (Donoghue et al., 2008; Le Douarin and Kalcheim, 1999). NC cells detach from the neural tube and migrate extensive distances along the stereotypical paths characteristic of their axial positions of origin. Upon arrival at their destinations, NC-derived cells participate in the morphogenesis of numerous organs and differentiate into a diverse array of cell types, including neurons and glia of the peripheral nervous system, bones and cartilage of the face, melanocytes of the skin, and VSMCs of the cerebral and pharyngeal vasculature (Crane and Trainor, 2006; Le Douarin and Kalcheim, 1999). NC cells that migrate into the pharyngeal arches 3–6 and into the heart are called cardiac NC cells. The cardiac NC originates from the region of the dorsal neural tube located between the otic pit and the 4th somite (Chan et al., 2004; Hutson and Kirby, 2007).

Studies in chickens and mice show that NC cell fates are influenced by signals emanating from their host tissues (Chen et al., 2012; Donoghue et al., 2008; Ferguson and Graham, 2004; Itasaki et al., 1996; Trainor and Krumlauf, 2000; Trainor et al., 2002a,b). In the pharyngeal arches, Notch signaling from the PAA endothelium mediates differentiation of the adjacent NC cell layers into VSMCs, and the region of active Notch around the PAA endothelium corresponds to the area within which NC cells undergo VSMC differentiation (High et al., 2008, 2007; Manderfield et al., 2012). However, mechanisms that limit the activation of Notch to the few NC cell layers proximal to PAA endothelium are unknown.

In our prior work, we made the unexpected observation that fibronectin 1 (*Fn1*) mRNA and protein are highly enriched in distinct regions of the mouse embryo, including regions corresponding to the developing NC and the pharyngeal arches 3, 4 and 6 (Mittal et al., 2010). Interestingly, many other ECM glycoproteins are also non-uniformly distributed during embryogenesis (reviewed in Astrof, 2013; Watt and Huck, 2013). This suggests that the highly localized distribution of ECM components during embryo development generates distinct microenvironments that can influence morphogenetic events in a spatially dependent manner. To test this hypothesis, we conditionally inactivated *Fn1* in the NC, and found that NC-synthesized *Fn1* regulates AAA morphogenesis and the differentiation of NC cells into VSMCs. Our studies indicated that NC-synthesized *Fn1* regulates VSMC differentiation by facilitating Notch signal transduction from the endothelium to the adjacent NC cells. Furthermore, we found that Notch activation

Fig. 1. *Fnl* mRNA and protein are downregulated in cardiac NC cells in *Fnl*^{lox/-}; *Tfp2a*^{IRESCre/+} mutant embryos. (A) Schematic left-side view of pharyngeal arch arteries 3, 4 and 6 connecting the heart with the dorsal aorta. Sections in all figures were cut along coronal planes (dotted line), the axes are marked. (B) Schematic view of a coronal section through the pharyngeal region. PAAs are numbered, axes are indicated. (C–C'') Controls. (E–E'') Mutants. (C–C'') and (E–E'') *Fnl* mRNA. In *Fnl*^{lox/-}; *Cre*⁺ mutants, *Fnl* mRNA is downregulated in the NC but not in the PAA endothelium (arrows). Magnified views of the 4th and 6th PAAs are shown in C', C'' and E', E''. Endoderm (en) is outlined by dotted lines. Arrows in C' and E–E'' indicate endothelial cells. (D,D',F,F') Neural crest (GFP⁺, blue), *Fnl* (red), *Pecam1* (green). *Fnl* protein is downregulated in *Fnl*^{lox/-}; *Cre*⁺ mutants. The native GFP fluorescence was extinguished by boiling sections in 10 mM citric acid (see supplementary Materials and Methods). See also Fig. S1. Scale bars: 100 μm.

in the NC cells surrounding the PAA endothelium is limited to the NC cells expressing *Fnl*.

In order to further understand the mechanisms by which *Fnl* regulates activation of Notch and the differentiation of NC cells into VSMCs, we sought to identify receptors on NC cells that could transduce *Fnl* signaling. Integrins are a major class of ECM receptors that connect the ECM with the actin cytoskeleton and transduce ECM signals into cells (Assoian and Schwartz, 2001; Giancotti and Tarone, 2003; Hynes, 2002; Schwartz and Assoian, 2001). Integrins are heterodimers comprising α - and β -subunits encoded by different genes; 18 genes encoding α -chains and 8 genes encoding β -chains give rise to 24 distinct integrin heterodimers with distinct and overlapping specificities for ECM ligands (Hynes, 2012). Here, we show that enrichment of *Fnl* around the PAA endothelium facilitates Notch activation and imparts the spatial specificity to Notch signaling by signaling through integrin $\alpha 5 \beta 1$. Our studies highlight the indispensable role of localized sources of *Fnl* in cardiovascular development, and suggest that specific, spatio-temporal expression patterns of ECM proteins are important for regulating distinct morphogenetic programs.

RESULTS

Ablation of *Fnl* in the NC results in cardiovascular abnormalities and perinatal lethality

Fnl mRNA becomes detectable in the cardiac NC at about the 8th–10th somite stage of mouse development, and its expression is maintained in the dorsal neural tube at least until the 23rd somite stage (Mittal et al., 2010). Studies using *Fnl*^{lox/lox} mice, a strain generated 14 years ago, show that the *Fnl* protein is downregulated within 24 h of *Cre* expression (Sakai et al., 2001).

However, 24 h is a significant fraction of the 19 day gestation period. Thus, to avoid potential problems with the perdurance of *Fnl* mRNA or protein after *Cre*-mediated recombination, we chose mouse lines in which *Cre* expression in the cardiac NC occurred early enough to ablate *Fnl* before *Fnl* mRNA was synthesized. Hence, we chose the transgenic *P3Pro-Cre* line and the knock-in *Tfp2a*^{IRESCre} strain for our experiments (Li et al., 2000; Macatee et al., 2003). In these strains, *Cre* expression in the cardiac NC is already evident by the 5th-somite stage, which is ~6 h prior to the onset of *Fnl* mRNA expression in that region (Mittal et al., 2010; Stottmann and Klingensmith, 2011). To conditionally ablate *Fnl* in the NC and its derivatives, we mated *Fnl*^{lox/lox} animals harboring either the *lacZ* (R26R/R26R) or *GFP* (*ROSA*^{mTmG}) reporters in a homozygous state with *Fnl*^{+/+}; *P3Pro-Cre*⁺ or *Fnl*^{+/+}; *Tfp2a*^{IRESCre/+} mice (Muzumdar et al., 2007; Soriano, 1999). The inclusion of reporters allowed the identification and tracking of NC descendants in control and mutant embryos. The relevant domains of *Cre* expression in these strains are schematically shown in Fig. S1A–B'. The use of *P3Pro-Cre* and *Tfp2a*^{IRESCre} strains resulted in efficient downregulation of *Fnl* mRNA (compare Fig. 1C–C'' with 1E–E'') and protein (compare Fig. 1D,D' with 1F,F') from the cardiac NC. In these and all other assays presented in this work, NC cells were identified by expression of GFP due to the presence of the *ROSA*^{mTmG} reporter allele (Muzumdar et al., 2007). For these and all other experiments involving immunofluorescence, the native GFP and tdTomato fluorescence was extinguished, as described in the Materials and Methods. *Fnl* protein remaining around the pharyngeal blood vessels in the mutants (Fig. 1F,F') is synthesized by the endothelium (arrows in Fig. 1E–E'').

Cardiovascular phenotypes of the *Fnl^{fllox/-}; P3Pro-Cre⁺* and *Fnl^{fllox/-}; Tfap2a^{IRESCre}* mutant embryos were comparable (Fig. 2, Fig. S2A–F and Tables S1 and S2). These mutants rarely survive the neonatal period (552 progeny were genotyped, Table S1) and exhibit a plethora of cardiovascular defects (Table S2). We also used the original *Wnt1-Cre1* strain to complement our experiments (Jiang et al., 2000), but we observed only one incidence of RERSA among 42 *Fnl^{fllox/-}; Wnt1-Cre1* embryos. Use of the new *Wnt1-Cre2* strain, which was constructed to avoid the drawbacks of the *Wnt1-Cre1* strain (Lewis et al., 2013), resulted in cardiovascular defects in 4 of 8 *Fnl^{fllox/-}; Wnt1-Cre2* mutants (Fig. S2G–L' and Table S2). One of these mutants had both RERSA and IAA-B. The difference in the incidence of AAA defects between *Fnl^{fllox/-}; Wnt1-Cre1* and *Fnl^{fllox/-}; Wnt1-Cre2* mutants is significant, $P=0.0001$ (two-tailed Fisher exact test). The NC is the common domain of Cre expression among the *Tfap2a^{IRESCre}*, *P3Pro-Cre* and *Wnt1-Cre2* strains (Fig. S1A', B', C'), indicating that the ablation of *Fnl* in the NC caused the observed phenotypes. Since the *Wnt1-Cre2* strain became available only recently, the majority of data in this paper were generated using the *Tfap2a^{IRESCre}* and *P3Pro-Cre* strains. The phenotypes of mutants generated using these strains were similar; therefore for clarity, we will designate *Fnl^{fllox/-}; Tfap2a^{IRESCre}* and *Fnl^{fllox/-}; P3Pro-Cre* embryos as *Fnl^{fllox/-}; Cre⁺* mutants and their *Cre⁺* littermate controls, as *Fnl^{fllox/+}; Cre⁺*, in the main text.

The most common malformations in *Fnl^{fllox/-}; Cre⁺* mutants were: (1) aberrant patterning of the aortic arch arteries (compare Fig. 2A,B with D,E; see Fig. S2). The incidence of AAA defects varied from 57% to 82% among the three strains assayed (Table S2); (2) formation of the intracardiac cartilage, similar to that described in Gao et al. (2010) occurred at 89–100% penetrance (Chen et al., 2015); and (3) the membranous ventricular septal defect (VSD; curved arrow in Fig. 2F): 29–42% penetrance (Table S2). Cardiac NC contributes mesenchymal cells to the thymus, regulating morphogenesis of this organ (Bockman and Kirby, 1984); consistent with that, we found that 44% of mutant embryos had mild defects in thymus development (Chen et al., 2015). Taken together, these phenotypes are characteristic of many other mouse mutants with defective development or function of the cardiac NC

(Hutson and Kirby, 2007). None of these malformations were observed in 267 control embryos examined at E14.5, E16.5 or E18.5.

NC cells arising at the same level of the neural tube as the cardiac NC, also contribute to the cardiac, enteric, sympathetic, parasympathetic and sensory nervous systems (Le Douarin and Kalcheim, 1999). However, with the exception of the palatal shelves, all other NC-derived lineages, such as dorsal root ganglia ($n=4/4$ mutants), enteric nervous system ($n=14/15$ mutants) and parasympathetic innervation of the heart and the diaphragm ($n=6/6$ mutants) developed grossly normally in *Fnl^{fllox/-}; Cre⁺* mutants (Fig. S2M–T). Cleft palates were found in all *Fnl^{fllox/-}; Tfap2a^{IRESCre}* mutants and in 4 out of 5 *Fnl^{fllox/-}; Wnt1-Cre2* mutants (Fig. S2U–X). These findings indicate that NC-derived *Fnl* is specifically required for the development of a narrow subset of the cranial NC.

NC-derived *Fnl* is required for the differentiation of NC cells into vascular smooth muscle cells

AAA defects in *Fnl^{fllox/-}; Cre⁺* mutants generated using the *Tfap2a^{IRESCre}*, *P3Pro-Cre* or *Wnt1-Cre2* strains included RERSA, interrupted aortic arch type B (IAA-B), hypoplastic aortic arch and the right-sided aortic arch (Fig. 2, Fig. S2, Table S2); in 6 of 43 *Fnl^{fllox/-}; Cre⁺* mutants, RERSA and IAA-B occurred concurrently. These defects are specific to abnormal development of the 4th pair of PAAs (Stoller and Epstein, 2005) and could be due to either defective PAA formation or defective remodeling of the well-formed PAAs into the AAAs (Conway et al., 2003). Injection of black India ink into the hearts of control and mutant embryos isolated at E10.5 showed that the three pairs of PAAs formed normally ($n=3$) (Chen et al., 2015). Similarly, examination of histological sections in $n>10$ mutants and controls 1 day later, at E11.5, indicated that all of the PAAs were well formed in the mutants (e.g. compare Fig. 3A,E). Therefore, the AAA defects observed in our mutants at E14.5–E16.5 were due to pathological regression of the initially well-formed 4th pair of PAAs. These phenotypes are analogous to other mutants with defective development of the cardiac NC (Hutson and Kirby, 2007). In such mutants the originally well-formed 4th pair of PAAs regressed because of either (a) insufficiency in cardiac NC cell population or (b) defective differentiation of the cardiac NC into VSMCs (Conway et al., 2003; Stoller and Epstein, 2005).

Consistent with our previous studies showing that *Fnl* was not required for NC migration in global *Fnl*-null mutants (Mittal et al., 2010), the deletion of *Fnl* in NC cells did not impair NC migration (compare Fig. S3A–B' with C–D"). However, unlike in the global *Fnl*-null embryos, *Fnl* synthesized by the NC was not required for NC cell survival (Fig. S3B", D"), suggesting that other cellular sources of *Fnl* regulate NC survival.

At E11.5, population densities of NC-derived cells in the control and mutant pharyngeal arches were comparable (compare Fig. 3A,E, blue; quantified in Table S3). However, the coverage of the 4th pair of PAAs with VSMCs was defective in 17 of 25 *Fnl^{fllox/-}; Cre⁺* mutants (compare Fig. 3A–D with E–H; quantified in Fig. S4). Four VSMC markers were assayed, α SMa (*Acta2*), SM22 α (*Tagln1*), calponin (*Cnn1*) and smooth muscle myosin heavy chain 11 (*Myh11*), and we found coordinated downregulation of all of these markers in cardiac NC-derived cells in *Fnl^{fllox/-}; Cre⁺* mutants (Fig. 3E–H). As expected, the development of VSMCs around the dorsal aorta (DA) was not affected in our mutants (Fig. 3A,E) because these VSMCs are derived from the mesodermal progenitors and not from the NC.

Vascular expression of the ECM protein fibulin-1, which is required for the development of the cardiac NC and AAA

Fig. 2. *Fnl^{fllox/-}; Tfap2a^{IRESCre}* mutants develop defects in AAA morphogenesis and ventricular septation. (A–C) Controls; (D–F) mutants. Small arrow in D indicates missing aortic arch (AA) in the mutants. Arrow in E indicates RERSA (retroesophageal right subclavian artery), originating from the dorsal aorta (dAo). (C,F) Coronal sections through the equivalent levels of control (C) and mutant (F) hearts show the presence of the ventricular septal defect (VSD, curved arrow in F) in the mutants. AA, aortic arch; dAo, dorsal aorta; lca, rca, left and right carotid arteries; lsa, rsa, left and right subclavian arteries; PT, pulmonary trunk; a, aortic valve; m, mitral valve; LV and RV, left and right ventricles. See also Fig. S2. Scale bars: 200 μ m.

Fig. 3. NC-derived Fn1 is required for the differentiation of NC cells into VSMCs *in vivo*. Coronal sections of control (A–D, I–L) and mutant (E–H, M–P) E11.5 embryos. Analyses of VSMC marker expression in control (A–D) and mutant (E–H) embryos show deficient expression of VSMC markers in NC cells (GFP⁺, blue) surrounding the PAAs in the mutants. Boxed areas in A and E are expanded in A'–A'' and E'–E''. The expression of ECM proteins fibulin-1 and laminin γ 1 are comparable around the PAAs in controls (I–J') and mutants (M–N'). Proliferation (K,O) and survival (L,P) of NC cells around the PAAs is not affected in the mutants. Axes are marked. Pharyngeal arch arteries are numbered. DA, dorsal aorta; R4, right fourth PAA. Native GFP fluorescence was extinguished by boiling sections in 10 mM citric acid (see supplementary Materials and Methods). For additional NC analyses at E9.5, see Fig. S3. For quantification of VSMC coverage at E11.5, see Fig. S4. Scale bars: 100 μ m in A,E; 50 μ m in all other panels.

morphogenesis (Cooley et al., 2008) was not affected in our mutants (Fig. 3I–I', M–M'') and neither was the expression of laminin γ -1 (Fig. 3J–J', N–N''), which is a component of vascular basement membranes (Yurchenco, 2011). We also did not observe differences in activation of SMAD2/3 and SMAD1/5/8 between controls and mutants (Fig. S6). Proliferation and survival of NC cells surrounding the PAAs (Fig. 3K,L,O,P) were also not affected in the mutants, Table S3. Taken together, our data indicate that Fn1 synthesized by NC-derived cells is required for the differentiation of NC cells into VSMCs. Furthermore, these data suggest that the mechanisms of Fn1-mediated NC-to-VSMC differentiation do not involve the regulation of ECM deposition or signaling by the TGF β family of proteins.

Remodeling of the PAAs observed in wild-type embryos involves stage-dependent, stereotypical regression of the right 6th PAA and partial regression of the right 4th PAA, which gives rise to a small segment of the right subclavian artery (Hutson and Kirby, 2007); the left 4th PAA persists and gives rise to the aortic arch. The left 6th PAA persists during fetal development and gives rise to the ductus arteriosus (Hutson and Kirby, 2007). By contrast, in animal models with cardiac NC deficiency, PAA regression occurs at random (Leatherbury et al., 1990; Nishibatake et al., 1987; Olaopa et al., 2011; Porras and Brown, 2008). This leads to variable aberrations in the final configuration of the AAAs, similar to the phenotypes observed in our mutants (Table S2, Fig. 2 and Fig. S2). Consistent with these findings, we observed that NC differentiation into VSMCs was affected on the left, right or both sides of the mutant embryos (Fig. S4). VSMC deficiency around the left 4th PAA is expected to result in the regression of this PAA, and give rise

to the interrupted aortic arch (IAA-B). VSMC deficiency around the right 4th PAA is expected to result in the regression of the right 4th PAA and to give rise to RERSA, and we observed IAA-B, RERSA or both IAA-B and RERSA in *Fn1*^{lox/-}; *Cre*⁺ mutants (Fig. 2, Fig. S2 and Table S2). Taken together, our studies indicate that defective morphogenesis of AAAs in *Fn1*^{lox/-}; *Cre*⁺ embryos result from the reduced differentiation of cardiac NC cells into VSMCs and that the NC-derived source of Fn1 plays a fundamental role in regulating cardiovascular morphogenesis.

NC-synthesized Fn1 regulates the differentiation of NC cells into smooth muscle cells in an NC cell-autonomous manner

On their way to pharyngeal arches, NC cells migrate through the cranial mesoderm that expresses *Fn1* (Mittal et al., 2010; Peters and Hynes, 1996). NC cells directly adjacent to the PAA endothelium within the pharyngeal arches are exposed to endothelial Fn1 (Fig. 1C–D', E–F'). Nevertheless, these paracrine sources of Fn1 are not sufficient to support the differentiation of NC cells into VSMCs and AAA morphogenesis (Fig. 2A,B,D,E, Fig. S2A–K' and Fig. 3). Taken together, these data suggest that NC-derived Fn1 mediates differentiation of NC cells into VSMCs in NC cell-autonomous manner. In order to test this hypothesis directly, we isolated NC cells from one of two sources: from a fragment of the neural tube (NT) located between the otic pit and the 4th somite and corresponding with the origin of the cardiac NC (Fig. 4A,B) or from the pharyngeal arches 3–6 containing cardiac NC cells, including those destined to give rise to PAA VSMCs (Fig. 4C,D). In these assays, NC cells were identified by the expression of GFP due

Fig. 4. Fn1 synthesized by the NC regulates the differentiation of NC cells into smooth muscle cells *in vitro*. NC cells were cultured under smooth muscle differentiation conditions. (A,B) Cardiac NC cells isolated from control (A) and mutant (B) neural tubes at E8.5. NC cells are GFP⁺ (green). Note prominent α SMA⁺ stress fibers (red) in controls (A) and their absence in mutant NC cells (B). Arrows indicate NC cells. GFP⁺ α SMA⁺ cells (arrowheads) are mesodermal cells co-isolated with the NC. NC cells from control (C) and from mutant embryos (D) isolated from the pharyngeal arches 3–6 at E9.5. Arrows indicate NC cells (green), arrowheads indicate mesodermal cells. Calponin (red) is expressed by control but not by mutant NC-derived cells. (E) Analyses of SMC differentiation in NC cells isolated from a single embryo are plotted individually. A total of 813 NC cells were analyzed from 3 *Fn1*^{flx/+}; *Cre*⁺ mutant embryos and 676 NC cells were analyzed from 3 control embryos. (F) 963 NC cells from 7 *Fn1*^{flx/+}; *Cre*⁺ control embryos and 892 NC cells from 5 *Fn1*^{flx/-}; *Cre*⁺ mutant embryos were analyzed. (G) NC cells isolated from the pharyngeal arches at E9.5 were cultured on coverslips coated with the indicated ECM proteins and stained to detect α SMA. Each data point is collected from one cultured embryo. Culture of *Fn1*-deficient NC cells on plasma or cellular Fn1 did not rescue smooth muscle differentiation in these cells. A total of 973 control and 1175 mutant NC cells plated on collagen 1 were imaged and quantified; 780 control and 847 mutant NC cells plated on pFn1 were imaged and quantified, and 843 control and 1062 mutant NC cells plated on cFn1 were imaged and quantified. Statistics were performed using two-tailed, unpaired Student's *t*-test with Welch's correction for unequal s.d. Means $\pm$ s.d. are shown. Scale bars: 50 μ m.

to the presence of the *ROSA*^{mTmG} reporter allele (Muzumdar et al., 2007). Expression of α SMA (*Acta2*) or calponin (*Cnn1*) was used as a readout of smooth muscle differentiation. These experiments demonstrated that *Fn1*-deficient NC cells were impaired in their differentiation into smooth muscle cells *in vitro* (Fig. 4A–D, quantified in Fig. 4E,F).

Fn1 protein is highly evolutionarily conserved among species (Hynes, 2012) and isolated *Fn1* proteins from different species are used interchangeably *in vitro*. In all of the *in vitro* experiments described above, NC cells isolated from control and mutant embryos were cultured in the presence of 10% fetal bovine serum and contained plasma *Fn1*, one of the most abundant serum proteins. However, the presence of plasma *Fn1* was not sufficient to restore the full smooth muscle differentiation potential to *Fn1*-deficient NC cells (Fig. 4E,F). It is important to note that the differentiation of control NC cells into smooth muscle cells in the presence of *Fn1*-depleted FBS was minimal in both control and mutant NC cultures (data not shown). This latter observation is consistent with the studies described by Costa-Silva et al. (2009), which suggested that plasma *Fn1* potentiates the differentiation of NC cells into VSMCs.

Plasma *Fn1* is different from *Fn1* synthesized by NC cells, since virtually all embryonic forms of *Fn1* include the EIIIA and EIIIB alternatively spliced exons at mid-gestation, whereas plasma *Fn1* is devoid of both (Astrof et al., 2007; Hynes, 1990; Peters and Hynes, 1996). Our previous genetic studies indicated that EIIIA[−]EIIIB[−] forms of *Fn1* were insufficient to support normal embryonic development, and that deletion of both the EIIIA and EIIIB exons from *Fn1* led to NC-related cardiovascular defects, despite the fact that EIIIA[−]EIIIB[−] *Fn1* in these mutants was synthesized at levels similar to those of wild-type *Fn1* in control embryos (Astrof et al., 2007). In addition, soluble plasma *Fn1* in culture medium could be in a different conformation than the

solid-state *Fn1* present in ECM or adsorbed to tissue culture plates. To test whether *Fn1*-coated glass slides could rescue smooth muscle differentiation in *Fn1*-deficient NC cells, we plated control and mutant NC cells on glass coverslips coated with collagen 1, human plasma *Fn1* or human cellular *Fn1* containing EIIIA and EIIIB splice variants (Fig. 4G). However, consistent with our *in vivo* data, *Fn1* provided in trans did not rescue smooth muscle differentiation defects in *Fn1*-deficient NC cells (Fig. 4G). These findings indicate that NC-derived *Fn1* regulates smooth muscle differentiation in a NC cell-autonomous manner.

NC-synthesized *Fn1* regulates Notch signaling

Several pathways are known to regulate the differentiation of NC-derived cells into VSMCs around PAAs 3–6 (Arnold et al., 2013; High and Epstein, 2008; Kaartinen et al., 2004; Li et al., 2005; Oh et al., 2005; Vallejo-Illarramendi et al., 2009). Among these, the role of Notch signaling has been particularly well studied (High and Epstein, 2008; High et al., 2008, 2007; Manderfield et al., 2015, 2012). Active Notch is an upstream regulator of NC differentiation into VSMCs (High et al., 2007; Manderfield et al., 2012). Prior experiments indicated that Notch signal is transduced from PAA endothelial cells to the adjacent NC-derived mesenchyme, leading to the expression of Notch target genes *Jagged1*, *Hey1* and *Hey2* in the NC. Notch signal is then relayed from one NC cell layer to the next as a result of induction of *Jagged1* in these cells – a process termed lateral induction (Eddison et al., 2000; Manderfield et al., 2012; Ross and Kadesch, 2004). In this process, *Jagged1* expressed by the proximal NC cells binds Notch expressed in next NC cell layer, which activates Notch signaling. The relay of Notch signal through the consecutive NC cell layers leads to smooth muscle gene expression and VSMC differentiation in those NC cells that are marked by the activated Notch (Boucher et al., 2011; Doi et al.,

2006; High et al., 2008; Manderfield et al., 2012; Noseda et al., 2006; Tang et al., 2008). However, the Notch signal is not relayed through the indefinite number of NC cell layers, but is confined to a few NC cell layers nearest the PAA endothelium (High et al., 2007). How this relay is terminated is unknown (Manderfield et al., 2012).

We noticed that the expression domains of *Fnl* and *Jagged1* proteins overlapped and diminished coordinately with increasing distance from the PAA vessel lumen (Fig. 5A–E). The expression of *Fnl* mRNA is also enriched in NC layers proximal to the PAA

endothelium (Fig. 1C–C'') and this expression pattern corresponds with the mRNA expression of other downstream targets of Notch – *Hey1* and *Hey2* (Fig. 5J,K and Fig. 6I–J'). These data show that Notch signaling around the PAA endothelium is mainly active within the NC cell layers that express *Fnl*.

These observations prompted us to ask whether *Fnl* regulated Notch signaling in the NC. To answer this question, we investigated the expression of Notch transcriptional targets *Jagged1*, *Hey1* and *Hey2*, as well as the expression of the active form of Notch – the

Fig. 5. *Fnl* regulates Notch signaling in NC cells surrounding the PAAs. (A–E) The *Fnl* (red) and *Jagged1* (green) proteins are co-enriched in NC cells surrounding the PAA endothelium. Fluorescence intensity along the line in D is plotted in E. (A–G', J–M) Controls; (H–I', N–Q) mutants. *Jagged1* fluorescence (green) (F,H) is shown in a separate channel (F',H'). White arrows indicate the extent of *Jagged1* expression around the PAA. (F',H') *Jagged1* fluorescence measured along the red lines is shown in F' and H' using the plot profile function in ImageJ. Each peak of fluorescence occurs at cell borders. In control (F–F'), *Jagged1* fluorescence is detectable over four cell borders; in the mutant (H–H'') *Jagged1* expression wanes at the third cell border. The first cell border occurs at the endothelial–NC interface. (G,G',I,I') NICD in the nuclei of NC cells surrounding the right 4th PAA in control (G,G', arrowheads). NICD expression in the mutant is mainly confined to the PAA lumen (I', arrows). (J–Q) *In situ* hybridization. In controls (J–K), *Hey1* and *Hey2* are expressed in the PAA endothelium and in adjacent NC cells. In the mutants, *Hey1* and *Hey2* expression is confined mostly to the endothelium (arrows) (N,O). The expression patterns of *Notch1* and *Notch3* are similar in controls (L,M) and in the mutants (P,Q). Endoderm (en) is outlined by the dotted lines. Axes are shown. Scale bars: 50 μ m in J–Q; 30 μ m in all other panels.

Fig. 6. Integrin $\alpha 5\beta 1$ regulates Notch signaling and VSMC differentiation in NC-derived cells. Coronal sections through E11.5 *Itga5^{fllox/+}; Tfp2a^{IRESCre/+}* control (A–D', I–L) and *Itga5^{fllox/-}; Tfp2a^{IRESCre/+}* mutant embryos (E–H', M–P). NICD (green) localizes to nuclei within multiple layers of NC cells (GFP⁺, blue, arrows) in controls (A, A') but in the mutants (E, E'), NICD is mainly confined to the endothelium, arrowheads. Arrows indicate NICD⁺ NC cells. (A', E') α SMA and (B, F) calponin are downregulated in the mutants. (C–D', G–H') Expression of α SMA and Jagged1 are coordinately downregulated in the mutants (G–H'). (C–D') Views of the same control section. (G–H') Views of the same mutant section. Arrows in D, D', H', H' indicate NC cells expressing Jagged1. Arrowheads in D, D', H', H' indicate endothelial cells expressing Jagged1. Endoderm (en) is outlined by the dotted white lines in D, D' and H, H'. Note that Jagged1 staining in the mutants is mainly confined to the endothelial–NC cell border (dotted brown line). (I–J', M–N') *Hey1* and *Hey2* mRNAs are downregulated in the mutants (M–N'). Compare area between the arrows in J' and N'. The outlined boxes in J and N are expanded in J', N'. (K, L, O, P) Expression of *Notch1* and *Notch3* in NC-derived cells surrounding the PAAs were not affected in the mutants. K, L are serial sections to C–D'. O, P are serial sections to G–H'. Scale bars: 50 μ m.

Notch intracellular domain (NICD) – in NC cells surrounding the 4th pair of PAAs in *Fnl^{fllox/-}; Cre⁺* mutants and controls at E11.5. For these analyses, we chose those *Fnl^{fllox/-}; Cre⁺* mutants in which α SMA expression in the NC around the PAAs was downregulated and used their littermate controls for comparisons (Fig. 5F–Q). Our experiments indicated that the expression of Jagged1 was downregulated in 5 of 6 *Fnl^{fllox/-}; Cre⁺* mutants with defective VSMC differentiation (compare Fig. 5F, F' with H, H'). Moreover, compared with the mutants, expression of Jagged1 in controls was maintained over a wider number of NC cell layers surrounding the PAAs (compare Jagged1 intensity profiles in Fig. 5F', H', each peak is Jagged1 fluorescence at consecutive cell borders). Similarly, NICD was expressed in multiple NC cell layers surrounding the 4th PAA in controls (Fig. 5G, G', arrowheads). By contrast, the expression of NICD in the NC was downregulated in all 3 of 3 examined *Fnl^{fllox/-}; Cre⁺* mutants (Fig. 5G, G', I, I') and was mainly confined to the endothelial cell layer (Fig. 5I', arrows). *Hey1* and *Hey2* mRNAs were downregulated in 4 of 4 examined *Fnl^{fllox/-}; Cre⁺* mutants (Fig. 5J, K, N, O).

Antibodies against the activated form of Notch (NICD) recognize cytoplasmic domains of Notch1 and Notch3. To test whether Fnl

regulated Notch signaling through expression of *Notch1* and *Notch3*, we performed *in situ* hybridization to detect the expression of these receptors in the mutants with downregulated expression of α SMA and Jagged1. These experiments showed that *Notch1* and *Notch3* were expressed at similar levels in controls and *Fnl^{fllox/-}; Cre⁺* mutants, $n=3/3$, (Fig. 5L, M, P, Q). These findings suggested that Fnl regulates Notch signaling rather than the expression of Notch receptors.

Taken together, our studies demonstrated that NC-synthesized *Fnl* regulates Notch signaling in NC cells around the PAAs, and showed that active Notch signal is confined to the region of NC cells enriched in Fnl protein. These results are consistent with the idea that the enrichment of *Fnl* mRNA and protein in the NC cell layers adjacent to the PAA endothelium imposes a spatial specificity to Notch signaling, and limits Notch signaling and NC-to-VSMC differentiation to this region.

Fnl regulates activation of Notch and NC differentiation into VSMCs by signaling through integrin $\alpha 5\beta 1$

If Fnl regulates the differentiation of NC cells into VSMCs in a NC cell-autonomous manner, NC cells must express receptors that

transduce Fn1 signals regulating Notch signaling and NC-to-VSMC differentiation. NC cells are known to express a number of Fn1 receptors, including α v-, α 4- and α 5-containing integrin heterodimers (Grazioli et al., 2006; Haack and Hynes, 2001; Testaz et al., 1999). Integrin α 5 β 1 is thought to be a major Fn1 signal transducer during early to mid-gestation (George et al., 1997, 1993; Mittal et al., 2013, 2010; Pulina et al., 2014, 2011; Takahashi et al., 2007; Yang et al., 1999, 1993). Therefore, we asked whether integrin α 5 β 1 was required for activation of Notch and differentiation of NC-derived cells into VSMCs. Conditional deletion of integrin α 5 in the NC using the same Cre-expressing strains as above resulted in defective differentiation of the cardiac NC cells into VSMCs in 11 of 20 integrin α 5 mutants (*Itga5*^{fllox/-}; *Cre*⁺), assayed either by expression of α SMA or calponin (compare red signal in Fig. 6A–C with E–G), quantified in Fig. S5. To test whether Notch signaling in the NC was also dependent on integrin α 5, we examined Notch activation in *Itga5*^{fllox/-}; *Cre*⁺ mutants exhibiting defective VSMC differentiation. Similar to *Fnl*^{fllox/-}; *Cre*⁺ mutants, expression of NICD was limited to the immediate vicinity of the PAA endothelium in 4 of 4 *Itga5*^{fllox/-}; *Cre*⁺ mutants, whereas in controls, NICD was present in multiple NC cell layers (compare green signal in Fig. 6A,A' with E,E'). As with *Fnl*^{fllox/-}; *Cre*⁺ mutants, we found that Jagged1 expression was limited to the immediate vicinity of the PAA endothelium in 5 of 5 integrin *Itga5*^{fllox/-}; *Cre*⁺ mutants (compare Fig. 6D,D' with H,H'). Consistent with these findings, *Hey1* and *Hey2* mRNA was downregulated in 4 of 4 *Itga5*^{fllox/-}; *Cre*⁺ mutants (compare Fig. 6I–J' with M–N'). Expression of Notch1 and Notch3 was not affected in *Itga5*^{fllox/-}; *Cre*⁺ mutants with defective expression of α SMA and Jagged1 (Fig. 6K,L,O,P). These findings indicated that expression of integrin α 5 by NC cells is required for Notch signaling in the NC and differentiation of NC cells into VSMCs.

To test whether impaired Notch signaling was the cause of defective smooth muscle differentiation in integrin- α 5-deficient NC cells, we asked whether activation of Notch in mutant NC cells would restore their ability to differentiate into VSMCs. NC cells isolated from *Itga5*^{fllox/-}; *Cre*⁺ mutants lack integrin α 5 β 1 (compare Fig. 7A–A" with B–B") and exhibit defective smooth muscle differentiation, assayed by the expression of α SMA or calponin (Fig. 7C,D, quantified in G, 'not infected' columns). However, activation of Notch signaling in integrin- α 5-deficient NC cells by expression of the Notch1 intracellular domain N1ICD (Tang et al., 2008) – but not of control proteins – restored smooth muscle differentiation in these cells (Fig. 7E–G), indicating that integrin α 5 regulates NC differentiation into VSMCs by activating Notch signaling.

Our findings are consistent with the model that NC-synthesized Fn1 regulates the activation of Notch and VSMC differentiation by signaling through integrin α 5 β 1 expressed by the cardiac NC. We hypothesize that as the PAAs grow in diameter between E10.5 and E11.5 stages of development, a morphogen secreted by the PAA endothelium induces high levels of Fn1 expression in NC cells adjacent to the PAA endothelium and that the region of Fn1 expression in the NC is determined by the diffusion/threshold levels of this morphogen (Fig. 7H). Alternatively, *Fnl* transcription in the NC could be induced by mechanical tension arising due to the increasing hemodynamic shear stress on the endothelium in the growing PAAs (Bordeleau et al., 2015; Chiquet et al., 2003; Liu et al., 2000). Regardless of how Fn1 is induced, our studies support the hypothesis that enriched expression of *Fnl* in NC cells around the 4th pair of PAAs imposes a spatial specificity on Notch activation and VSMC

differentiation in the NC, and regulates the complex process of PAA remodeling.

DISCUSSION

Role of Fn1 and integrin α 5 in NC development and cardiovascular morphogenesis

Our previous studies revealed that *Fnl* mRNA and protein are expressed in non-uniform, dynamic patterns during embryogenesis (Mittal et al., 2010). The high evolutionary conservation of *Fnl* and the essential role of Fn1 in cardiovascular development suggested that enriched expression of Fn1 in specific embryonic regions is biologically significant. The studies described in this paper and in our earlier publication (Chen et al., 2015) reveal requisite, cell type-specific functions of Fn1 in embryogenesis and cardiovascular development.

We used three different strains of mice, the *P3Pro-Cre* and *Wnt1-Cre2* transgenic lines and the *Tfap2a*^{IRESCre} knock-in mice to determine the role of Fn1 synthesized by the NC. These experiments demonstrated that specific expression of Fn1 in the NC is required for the development of the palate and the cardiovascular system. Furthermore, we showed that NC-synthesized Fn1 was specifically required for the asymmetrical remodeling of the PAAs into the AAAs by regulating Notch signaling and differentiation of NC-derived cells into VSMCs.

Despite the presence of Fn1 at the interface between the PAA endothelium and NC cells in *Fnl*^{fllox/-}; *Cre*⁺ mutants, endothelial Fn1 was not sufficient to promote VSMC differentiation in the adjacent NC, demonstrating the importance of NC cell-specific Fn1. Unlike in global *Fnl*-null embryos, NC cell survival and proliferation were not affected in the conditional *Fnl*^{fllox/-}; *Cre*⁺ mutants, demonstrating that Fn1 synthesized by other embryonic cell types is sufficient to support NC proliferation and survival but not their differentiation into VSMCs.

Studies by Costa-Silva et al. (2009) showed that plating wild-type NC cells on plasma fibronectin-coated surfaces promoted the differentiation of NC cells into smooth muscle cells. Our data support these findings, since we observed only minimal smooth muscle differentiation of wild-type NC cells in the absence of plasma Fn1. However, we show that plasma Fn1 is not sufficient to rescue smooth muscle differentiation in *Fnl*-null NC cells. Together with the results of NC cell culture, our genetic studies *in vivo* demonstrate the requirement for the NC cell-specific source of Fn1 in the differentiation of NC cells into VSMCs.

Fn1 is alternatively spliced and we previously showed that the presence of EIIIA or EIIIB alternatively spliced exons in *Fnl* was necessary for NC development and cardiovascular morphogenesis (Astroff et al., 2007). However, both EIIIA⁺ and EIIIB⁺ forms of Fn1 are present around the PAAs (Astroff et al., 2007), and both the PAA endothelium and the NC synthesize EIIIB⁺EIIIA⁺ Fn1 (our unpublished data). Thus, differences in the alternative splicing are unlikely to explain why endothelial Fn1 does not compensate for the absence of NC-synthesized Fn1. One would expect that in *Fnl*^{fllox/-}; *Cre*⁺ mutants, the total levels of Fn1 are lower at the interface of the PAA endothelium and the NC relative to controls; however, a simple decrease in Fn1 levels cannot explain defects observed in *Fnl*^{fllox/-}; *Cre*⁺ mutants, given that a 50% decrease in Fn1 protein levels is sufficient to support normal embryogenesis and adult homeostasis in *Fnl*^{+/-} mice. Addition of ectopic Fn1 (purified from either plasma or cellular sources) *in vitro* did not rescue NC-to-VSMC differentiation in *Fnl*-deficient NC cells, supporting the notion that it is the synthesis of Fn1 by the NC that is important for VSMC differentiation of NC cells, rather than the overall levels of Fn1 protein. These results suggest that cell-autonomous and

Fig. 7. Activation of Notch rescues smooth muscle differentiation in integrin- α 5-deficient NC cells. (A–A'') Control and (B–B'') mutant NC cells (green, arrows) and mesodermal cells (arrowheads). Integrin α 5 (red) and NC cells (GFP⁺, green), nuclei (DAPI, blue). (C,D) Control and integrin- α 5-deficient NC cells, stained for GFP (green) and calponin (red). Arrows indicate NC cells. GFP⁺ mesodermal cells (arrowheads) act as internal positive controls for calponin staining. (E) Mutant NC cultures from pharyngeal arches 3–6 infected with adenovirus encoding control NDRG1-FLAG protein (blue). Arrows indicate NC cells (GFP⁺, green). Note that mesodermal cells (arrowheads) but not NC cells express calponin (red) in the mutant. The composite staining in E is split into separate channels in E' and E''; dashed boxes are magnified in Ea, E'a and E''a. (F) Mutant NC cells (GFP⁺, green) from the pharyngeal arches 3–6 infected with adenovirus encoding N1ICD (nuclear localized, blue). Straight arrows indicate infected NC cells, curved open arrows indicate non-infected NC cells and an arrowhead indicates a mesodermal cell. Note that N1ICD-infected mutant NC cells (straight arrows) but not the non-infected cells (curved open arrows) express calponin (red). The composite staining in F is split into separate channels in F' and F'', the dashed boxes are magnified in Fa, F'a and F''a. (G) Control or mutant NC cells were left non-infected or were infected with either control viruses or viruses expressing N1ICD. SMC differentiation was assayed by the detection of either α SMA or calponin. Statistics were performed using two-tailed, unpaired Student's *t*-test: ****P* < 0.0053; NS, not significant. Each data point is collected by analyzing NC cells isolated from one embryo. Mean and s.d. are plotted. For these experiments, we analyzed 798 non-infected controls NC cells isolated from 5 embryos, 575 control NC cells isolated from 4 embryos and infected with control virus, and 486 control NC cells isolated from 4 embryos and infected with N1ICD virus; 1201 non-infected mutant NC cells from 6 embryos, 716 mutant NC cells isolated from 5 embryos and infected with control virus, and 520 mutant NC cells isolated from 5 embryos infected with N1ICD virus. (H) Model. We hypothesize that as the PAA endothelial lumen increases between E10.5 and E11.5 stages of development, endothelium is induced to secrete a diffusible factor regulating *Fn1* expression in the NC-derived cells surrounding PAAs. This morphogen could also be in the form of mechanical force transduced from the endothelium to the NC due to the increased blood flow through the expanding PAA. *Morphogen could be a protein or mechanical force. Scale bars: 20 μ m in A–B''; 50 μ m in C,D; 40 μ m in E,F.

paracrine sources of Fn1 could engage different signaling pathways in the NC. Alternatively, differences between Fn1 proteins synthesized by the NC and endothelium could be due to potential variations in cell type-specific post-translational modifications of Fn1.

If NC-synthesized Fn1 signaled in an NC cell-autonomous manner, it would have to engage Fn1 receptors expressed by the NC (Testaz et al., 1999). Previous studies demonstrated that integrin α 5 β 1 is a major Fn1 receptor in early and mid-gestation mouse embryos (Chen et al., 2015; George et al., 1997, 1993; Mittal et al., 2013, 2010; Pulina et al., 2014, 2011; Takahashi et al., 2007; Yang et al., 1999, 1993). Therefore, we used conditional mutagenesis to ablate integrin α 5 in the NC. These studies showed that the expression of integrin α 5 β 1 by NC cells was required to facilitate the

differentiation of NC cells into VSMCs. Thus, our experiments suggested that NC-synthesized Fn1 regulates the differentiation of NC cells into VSMCs by engaging integrin α 5 β 1 expressed by NC cells in a cell-autonomous manner.

Much of what we know about the roles of Fn1 in cell biology has been gleaned from studies with ectopically supplied purified Fn1 proteins (Bae et al., 2014; Hynes, 1990; Schwartz, 2010). However, recent *in vivo* studies suggest that in addition to paracrine functions (Yoshino et al., 2014), Fn1 could also signal in a cell-autonomous manner (Cseh et al., 2010; Liu et al., 2010; Serres et al., 2014; Stenzel et al., 2011). By using genetic and cell biological approaches, the studies reported in this paper are the first to demonstrate the requisite, cell-autonomous role of Fn1 in the regulation of cardiovascular development. This discovery bears

significant implications for the fields of regenerative biology and tissue engineering by demonstrating that cell-specific synthesis of ECM can modulate distinct aspects of organ morphogenesis and that simply providing ECM in trans as an adhesive support may not elicit the appropriate cell signaling responses.

Early and late roles of Fn1-binding integrins in AAA morphogenesis

In our studies, we used mouse strains, in which the Cre recombinase is expressed early in the NC development (~5 somite stage) (Lewis et al., 2013; Olaopa et al., 2011; Stottmann et al., 2004); this is before the delamination of cardiac NC cells and prior to their arrival into the pharyngeal arches. Thus, our studies specifically address the role of Fn1 and integrin $\alpha 5$ in the differentiation of multi-potent NC cells into VSMCs. By contrast, Turner et al. (2015) used the *SM22 α -Cre* transgenic line to ablate integrins $\alpha 5$ and αv in smooth muscle lineages, including those derived from the NC. *SM22 α* is a marker of early smooth muscle differentiation. Thus, the downregulation of integrins $\alpha 5$ and αv in *Itga5/Itgav^{SM22-Cre}* double mutants has most likely occurred after the onset of VSMC differentiation in the NC, explaining the lack of VSMC differentiation defect in these mutants (Turner et al., 2015). Similarly, Turlo et al. (2012) used the *SM22 α -Cre* transgenic line to ablate integrin $\beta 1$ and showed that the expression of $\beta 1$ -containing integrin heterodimers, which include $\alpha 5\beta 1$, in smooth muscle cells was important for maintaining AAA VSMCs and AAA integrity. Taken together with the studies by Turlo et al. (2012) and Turner et al. (2015), our work demonstrates that signaling by Fn1 and integrin $\alpha 5\beta 1$ is essential for both the morphogenesis and maintenance of the AAAs: our studies establish the requisite role of Fn1 and integrin $\alpha 5\beta 1$ in the differentiation of NC cells into VSMCs, thereby regulating the remodeling of symmetrical PAAs into the AAAs. The work of Turlo et al. (2012) and Turner et al. (2015) demonstrated that following the differentiation of NC cells into VSMCs, signaling by $\alpha 5$ -, αv - and $\beta 1$ -containing integrin heterodimers is essential for maintaining VSMCs and the architecture of the AAA vessel wall.

The role of Fn1 and integrin $\alpha 5$ in VSMC development depends on the ontogeny of VSMC progenitors

VSMCs in diverse vascular beds arise from different progenitors. Known embryonic sources of VSMCs include the lateral and paraxial mesoderm, mesothelia and the NC (Jiang et al., 2000; Le Lievre and Le Douarin, 1975; Que et al., 2008; Rinkevich et al., 2012; Wasteson et al., 2008; Wilm et al., 2005). Studies by others and our lab indicated that integrin $\alpha 5$ is not required for the differentiation of mesodermal cells into VSMCs (Liang et al., 2014; Turner et al., 2014, 2015). Furthermore, addition of Fn1 to mesodermal VSMC precursors stimulated their proliferation and the synthetic phenotype and opposed their differentiation into smooth muscle cells (Bae et al., 2014; Hedin et al., 1988; Shi et al., 2014). This contrasts with the roles of Fn1 and integrin $\alpha 5$ in the differentiation of NC cells. Currently, it is not clear why signaling by Fn1 and integrin $\alpha 5$ differs between mesoderm- and NC-derived VSMC progenitors. However, it is widely known that VSMCs from different tissue sources can be distinguished on the basis of their gene expression profiles, the mechanisms regulating their differentiation and in their susceptibility to disease and injury (Cheung et al., 2012; Gittenberger-de Groot et al., 1999; Majesky, 2007; Michel et al., 2012; Pfaltzgraff et al., 2014; Ruddy et al., 2008). Furthermore, differences in genetic regulation of VSMC development between the mesoderm and NC contribute to pathological manifestations of congenital disorders such as Marfan

and Loeys–Dietz syndromes, both of which involve aneurisms that develop at the borders of mesoderm- and NC-derived VSMCs (Majesky et al., 2011; Ruddy et al., 2008). In the future, it will be instrumental to determine the mechanisms underlying distinct functions of Fn1 and integrin $\alpha 5$ in the differentiation of VSMCs from mesodermal and NC progenitors.

Fn1 and integrin $\alpha 5\beta 1$ regulate the differentiation of NC cells into VSMCs by activating Notch signaling

Activation of Notch signaling in NC cells surrounding the PAAs is essential for the differentiation of NC cells into VSMCs (High et al., 2008, 2007; Manderfield et al., 2012). In this paper, we show that Notch activation is limited to the field of NC cells expressing *Fn1* and that Fn1 facilitates activation of Notch by signaling through integrin $\alpha 5\beta 1$. How interactions between Fn1 and integrin $\alpha 5\beta 1$ regulate Notch signaling is not yet clear. However, it is known that signaling by integrins can regulate Notch activation both directly and indirectly. In *Drosophila*, integrin heterodimers containing $\beta 1$ regulate Notch activation by regulating its intracellular trafficking or processing (Gomez-Lamarca et al., 2014). Studies in *Drosophila* also showed that the activation of Notch occurs at the tips of basal filopodia and requires the activation of ezrin, Rac, Scar and actin polymerization (Cohen et al., 2010; De Jossineau et al., 2003). Signaling by Fn1 and $\alpha 5\beta 1$ is well known to activate Rac, the Wave/Scar complex and actin polymerization (reviewed by Huttenlocher and Horwitz, 2011). Thus, ablation of Fn1 or integrin $\alpha 5$ in the NC could interfere with Notch signaling by interfering with actin polymerization, formation of basal filopodia, or by altering the trafficking/processing of Notch. An indirect role of $\beta 1$ -containing integrin heterodimers in the activation of Notch was demonstrated in the chick (Rallis et al., 2010). These studies showed that $\beta 1$ integrins activate *Jagged1* transcription through ILK-mediated stabilization of β -catenin. Stabilized β -catenin directly binds and activates *Jagged1* promoters upon translocation into the nucleus (Estrach et al., 2006; Rallis et al., 2010). This is consistent with our observations that Notch signaling is active in cells that express *Fn1*, and that Notch signaling declines concomitant with the decrease in Fn1 levels.

Taken together, our studies highlight the requisite role of the NC-specific source of Fn1 during morphogenesis of the aortic arch arteries and raise many interesting questions: do NC- and endothelial-derived forms of Fn1 differ from each other? Do paracrine and autocrine sources of Fn1 engage different cellular signaling pathways? What are the mechanisms regulating *Fn1* expression in the NC and what are the intracellular pathways by which Fn1 and integrin $\alpha 5\beta 1$ regulate Notch signaling?

MATERIALS AND METHODS

Mouse strains and genotyping

Details of mouse strains used can be found in supplementary Materials and Methods. Genotyping was performed using PCR primers as described previously (Mittal et al., 2010; Sakai et al., 2001; van der Flier et al., 2010). All embryos up to E10.5 were staged by counting somites, older embryos were staged by the day of vaginal plug. All animal studies were approved by the Thomas Jefferson University Institutional Animal Care and Use Committee.

Histology

Histology, immunohistochemistry and β -gal staining were performed as described previously (Chen et al., 2015; Liang et al., 2014). For more details about the procedures and antibodies, see supplementary Materials and Methods.

In situ hybridization

In situ hybridization was carried out using *Fnl* (316951), *Hey1* (319021), *Hey2* (404651), *Notch1* (404641) and *Notch3* (425171) RNA probes synthesized by Advanced Cell Diagnostics (ACD). Detection was done using RNAscope 2.0 FFPE Assay Brown kit according to the manufacturer's protocol (ACD). After the signal was developed, sections were counterstained with Gill's hematoxylin.

Quantification of vessel coverage by VSMCs

VSMC coverage (Figs S4 and S5) was determined using coronal sections from control and mutant embryos dissected at E11.5. Quantification of 4–18 sections per pharyngeal arch per embryo was performed using ImageJ software. Equivalent numbers of sections were analyzed for each set composed of one control and one mutant embryo and 5–6 sets of control and mutant embryos were analyzed per experiment. To determine VSMC coverage, we calculated the fraction of vessel perimeter occupied by α SMA⁺ or SM22 α ⁺ signal.

Neural tube explant culture and immunofluorescent staining of NC cells

Control and mutant embryos were obtained by crossing *Fnl*^{+/−}; *Tfap2*^{IRESCre} females with *Fnl*^{fllox/fllox}; *ROSA*^{mT/mG} male mice. E8.5 embryos (15 somites) were dissected in PBS. To obtain integrin- α 5-deficient NC cells and their controls, we crossed *Itga5*^{+/−}; *Tfap2a*^{IRESCre} or *Itga5*^{+/−}; *P3Pro-Cre* females with *Itga5*^{fllox/fllox}; *ROSA*^{mT/mG} male mice. The neural tube (NT) from the otic placode to the fourth somite was dissected out and incubated in collagenase/dispase (100 μ g/ml; Roche, 11097113001) for 7 min at room temperature. The neural tube was microdissected from the surrounding mesenchyme and the surface ectoderm, and then longitudinally plated on 12 mm glass coverslips pre-coated with 100 μ g/ml collagen type I (BD Biosciences, 354249) in 4-well plates (Thermo Scientific, 12-566-350). To induce smooth muscle differentiation, explants were cultured for 3 days at 37°C and 5% CO₂ in high glucose DMEM (Invitrogen) containing 10% fetal bovine serum (BenchMark FBS, Gemini Bio-Products).

To culture NC cells from the pharyngeal arches 3–6 isolated from E9.5 mouse embryos, embryos were incubated with 150 μ g/ml collagenase/dispase for 3 min. Surface ectoderm was peeled off and pharyngeal arches 3–6 were dissected out, plated as above, then cultured in NC self-renewal medium for 4 days (Bixby et al., 2002). On the 5th day, NC cultures were digested using 0.25% trypsin into single cells and plated on 12 mm glass coverslips pre-coated with either 150 μ g/ml collagen I, 10 μ g/ml plasma Fn1 (BD Biosciences, 356008) or 10 μ g/ml cellular Fn1 (Sigma, F2518). We confirmed that cellular Fn1 but not plasma Fn1 contained the EIIIA domain by western blotting using anti-EIIIA antibody (Sigma, F6140).

Smooth muscle differentiation conditions and quantification

To induce smooth muscle differentiation, cells were cultured in DMEM containing 10% FBS at 37°C and 5% CO₂ until all cells attached (2 h). After this, NC cells were either left in the medium for the additional 48 h or treated with adenoviruses (see below) for 2 days. Cells were then fixed in 4% PFA for 20 min at room temperature, washed and blocked for 30 min with 10% normal donkey serum in PBS/0.05% Tween-20. Cells were incubated overnight at 4°C with primary antibodies diluted in blocking buffer. After a thorough washing step the next day, cells were incubated for 1 h at room temperature with secondary antibodies and mounted with ProLong Gold antifade. Images were captured with a Zeiss Axiovert inverted fluorescence microscope.

NC cultures were stained to identify NC-derived cells (GFP⁺, due to the presence of *ROSA*^{mTmG} reporter allele), smooth muscle cells (α SMA or calponin 1) and DAPI (nuclei). For infected cultures, cells were also stained to identify infected cells using antibodies directed against either the FLAG or V5 tags (for further details see supplementary Materials and Methods). All cells in each well were photographed at 20 $\times$ magnification and coded to conceal the identity of NC cell genotypes. The data were quantified without the knowledge of genotypes. Following quantification, the identity of the samples was decoded and results were analyzed using Prism 6 software (GraphPad). To quantify differentiation of untreated control and

integrin- α 5-deficient NC cells or NC cells infected with control or N1ICD-encoding viruses, we performed at least four independent experiments, all plotted in Fig. 7G.

Adenoviral infection

Adenoviruses expressing V5-tagged Notch 1 intracellular domain (N1ICD) were produced by the Viral Vector Core at the Maine Medical Center Research Institute (Tang et al., 2008). The N1ICD virus stock concentration was 1.3×10^{13} viral particles/ml. Control adenoviruses were produced using RAPAd CMV adenoviral expression system (Cell Biolabs, San Diego, CA, USA). Stock adenoviral concentration was 4×10^{11} pfu/ml. Viral stock solutions were diluted 1:1000 in DMEM containing 10% FBS and 300 μ l was used to infect the cells. Viruses were incubated with NC cells at 37°C and 5% CO₂ for 48 h. Cells were then fixed for 20 min with 4% PFA at room temperature, washed with PBS and stained using antibodies against GFP, α SMA or calponin, and V5 or FLAG tags.

Statistics

Data were analyzed by two-tailed, unpaired Student's *t*-tests or by two-way ANOVA, as indicated in figure legends utilizing Prism 6 GraphPad software. A *P*-value of less than 0.05 was considered significant.

Acknowledgements

We are grateful to Dr Anne Moon for TFAP2 α ^{IRESCre} mice, Dr Jeff Miner for providing P3Pro-Cre transgenic mice, which were generated in Dr Jon Epstein's lab, Dr Richard Hynes for providing integrin α 5 floxed mice prior to their publication, and Dr Reinhardt Fassler for Fn1 floxed mice. We thank Dr Karl Degenhardt for help with the interpretation of cardiac phenotypes and Dr Marion Cooley for the anti-Fibulin1 antibody. We thank Shuan-Yu Hou, Ahab Dababneh and Sonam Dhiman for technical assistance, and Dr Maria Yolanda Covarrubias of the Kimmel Cancer Center Bioimaging facility at the Thomas Jefferson University for assistance with confocal imaging. We thank Dr Jianxin Sun and the members of his laboratory for assistance with generating adenoviruses and for providing control adenoviruses used in these experiments. We thank Dr Igor A. Prudovsky for providing N1ICD adenoviral expression vector and Dr Nancy Chandler-Conrey and the Viral Vector Core at the Maine Medical Center Research Institute for production of N1ICD adenoviruses. We are grateful to Dr Nathan Astrof for critical reading of the manuscript, helpful discussion, and insightful suggestions. We also thank Tung Chan, Glenn Radice, Mary Hutson and Joshua Brickman for critical reading of the manuscript. We are especially grateful to Sydney Astrof for her curiosity and energy. We thank Jennifer Wilson from the TJU Writing Center for editorial assistance.

Competing interests

The authors declare no competing or financial interests.

Author contributions

Conceived and designed experiments: X.W. and S.A. Performed experiments: X.W. Analyzed data and generated figures: X.W. and S.A. Wrote the paper: X.W. and S.A.

Funding

This work was supported by the funding from the National Institutes of Health [NHLBI RO1 HL103920 to S.A.], American Heart Association Innovative Research Grant [12IRG9130012 to S.A.], the W. W. Smith Charitable Trust, and the funds from the Weizmann Institute of Science – Thomas Jefferson University Collaboration Program to S.A. X.W. was supported by an American Heart Association Postdoctoral Fellowship [12POST11750033 to X.W.]. Deposited in PMC for release after 12 months.
