FRAMEWORKS TO GUIDE CAREGIVER TRAINING

Transtheoretical Model (Prochaska et al., 1988)

- Family caregiver training requires that caregivers adopt new approaches to care. Understanding the level of caregiver readiness to learn and implement new strategies can inform the approach to training.
  - Caregivers with *low levels of readiness* may need more education about the disease and an understanding that troublesome behaviors are not intentional but a consequence of the disease.
  - Caregivers with *high levels of readiness* tend to be immediately receptive to learning and implementing strategies.

Competence-Environmental Press Framework (Lawton & Nahemow, 1973)

- Educating family caregivers to obtain that “just-right fit” between personal capabilities and environmental demands results in positive behaviors and enhanced quality of life for both the caregiver and the individual with dementia.
Cognitive Disabilities Model (Allen & Blue, 1998)

- Six Allen Cognitive Levels (ACL) that describe the complex and dynamic interaction between a person’s cognitive abilities and the context in which functional performance takes place.

- Based on the ACL, occupational therapists can
  - Teach caregivers how to match abilities with tasks.
  - Provide suggestions that facilitate the person’s best ability to function within the least restrictive environment.
MODELS FOR ANALYZING BEHAVIORS

**Need-Driven Behavior Model (NDB)** (Algase et al., 1996)

- Persons with dementia have difficulty expressing their needs.
- Behavior is the result of an attempt to meet a basic human need that is not currently being met.
- Background factors cannot be controlled, where current factors may be, but awareness and understanding of both help with behavior guidance.

**Progressively Lowered Stress Threshold (PLST)** (Hall & Buckwalter, 1987)

- Stress threshold is lower in persons with dementia.
- Behavior is a result of excess environmental stress and caused by increasing anxiety.
- A person’s stress threshold shrinks both during the course of dementia and over the course of the day.
The ABC model can be used to instruct the caregiver to identify the stimulus (activator) that triggers a specific behavior and clearly define and analyze the potential consequences. This includes both positive and negative behaviors.

In training, caregivers learn to evaluate each behavior to assess how often and for how long it occurs. Through this process, the caregiver can identify the specific activator(s) that can be enhanced, modified or eliminated.

The process is cyclical, and the consequence can become a new activator for behavior.

Teaching the problem solving process offers caregivers a skill to use when new situations occur after occupational therapy service or training is complete.
