Fatal airway obstruction from ACEI angioedema has been described but effective therapy has not been established. Intubation is sometimes required for progressive airway compromise. Ecallantide is a kallikrein pathway blocker and may offer benefit in reversing ACEI induced angioedema.

Case

- A 54 year old African-American male with a history of hypertension treated with lisinopril daily, recent cocaine abuse associated myocardial infarction, seizures and prostate cancer, presented with a 2 day history of facial and throat swelling along with dysphagia. He was treated in the emergency department with intravenous methylprednisolone, epinephrine and diphenhydramine. He was admitted, but angioedema progressed overnight, confirmed by laryngoscopy. ICU transfer and intubation was undertaken the next morning.

- The patient was 1014 hours. Chemistries were normal. Ecallantide 30mg was administered subcutaneously for airway protection. Tryptase level was 2.2 mg/L.

- Family history: No history of angioedema. Parents deceased.
- Social history: Denies current alcohol or recreational drug use.

- Physical Exam: Temp 98.8, Respiratory Rate 15, Heart Rate 61, Blood Pressure 130/80, and Oxygen Saturation 99% on ventilator.

- HEENT- Oral endotracheal tube, limited exam after intubation by Otolaryngology for airway obstruction and desaturation while sleeping.

- Respiratory- Lungs were clear and with good air entry on ventilator.

- Cardiac- Regular heart rate and regular rhythm with no appreciable gallops, murmurs, or rubs.

- Skin- There was no urticaria, other angioedema or rash.

- This presentation was supported in part by Dyax, Inc.

- The mechanism of ACEI angioedema is thought to be from blockade of angiotensin converting enzyme, the major enzyme for degradation of bradykinin.

- Bradykinin and substance P have been linked to the pathogenesis of ACEI induced angioedema. Angiotensin converting enzyme (ACE) is a kinase that breaks down bradykinin. The inhibition of ACE therefore leads to the inhibition of bradykinin catabolism. Bradykinin formation causes vasodilatation and increased vascular permeability by interaction with B-2 receptors. The inhibition of bradykinin catabolism thus leads to angioedema.

- Anti-histaminics, corticosteroids and epinephrine are ineffective in acute attacks of non-allergic angioedema. The mainstay of treatment currently is airway protection and supportive care. Theoretically, glucocorticoids could lead to a decrease in mucosal swelling. However, there is no demonstrated beneficial effect in patients with angioedema. Inhaled epinephrine may also be effective in laryngeal angioedema.

- Ecallantide is approved treatment of hereditary angioedema. It selectively and reversibly inhibits plasma kallikrein, preventing bradykinin generation. It is theorized that ecallantide can be used to treat other forms of kallikrein dependant angioedema.

- The length of hospitalization for patients with ACEI induced angioedema has ranged from 2 days to 4.8 days. Our patient self-extubated a few hours after emergency intubation and was discharged the next day after he remained stable overnight and without distress.

- This case suggests that ecallantide may indeed be effective in the cessation of ACEI induced angioedema. Additional randomized studies are underway to confirm these findings.
