The following article is reprinted with permission from Lands BioScience. It was originally published in Cell Cycle, Volume 7, Issue 9, pp. 1224-1230.

Abreviations: MO, antisense morpholino oligonucleotide; PFTα, pifithrin-α; Hpf, hours post fertilization; Kd, knock down; IR, ionizing radiation

Key Words: zebrafish, development, radiation effects, tumor suppressor protein p53, tumor suppressor protein p73, pifithrin-α

The p53 family of proteins contains two members that have been implicated in sensitization of cells and organisms to genotoxic stress, i.e., p53 itself and p73. In vitro, lack of either p53 or p73 can protect certain cell types in the adult organism against death upon exposure to DNA damaging agents. The present study was designed to assess the relative contribution of p53 to radiation resistance of an emerging vertebrate model organism, i.e., zebrafish embryos. Consistent with previous reports, suppressing p53 protein expression using antisense morpholino oligonucleotides (MOs) increased survival and reduced gross morphological alterations in zebrafish embryos exposed to ionizing radiation. By contrast, a pharmacological inhibitor of p53 function (Pifithrin-α (PFTα)) caused developmental abnormalities affecting the head, brain, eyes and kidney function and did not protect against lethal effects of ionizing radiation when administered at 3 hours post fertilization (hpf). The phenomenon is further highlighted off-target effects of the pharmacological p53 inhibitor PFTα related to inhibition of p73 function and essential roles of p73 at early but not later stages of zebrafish development.

Results and Discussion

Time- and dose-dependent effects of ionizing radiation on zebrafish embryo survival. Previously, we observed that radiation sensitivity of zebrafish embryos was different at distinct developmental stages and progressively decreased between 2 to 8 hours post fertilization (hpf). Here, we extend this earlier study by assessing embryo survival after exposure to increasing radiation doses up to 72 h after radiation. These experiments confirmed progressive radiosensitivity at successive stages of development (not shown). To determine the consequences of inhibiting translation of specific gene products by antisense MO kd for radiation resistance of the developing embryo, we performed all subsequent experiments at 24 hpf. This was based on the consideration that, at this time point, target protein expression is sufficiently suppressed by antisense MO kd and remains low for extended time periods up to 4 days post fertilization (dpf). Dose-dependent survival upon radiation exposure at 24 hpf revealed 100% lethality scored at 6–7 dpf (40 Gy) with a LD50 of 20 Gy. To monitor the effects of p53 expression on radiation sensitivity as it relates to both, mortality and tissue-specific effects, we thus performed experiments at 20 or 40 Gy.

Reduced p53 expression is associated with radioprotection of zebrafish embryos. Zebrafish embryos harboring homozygous missense p53 mutations exhibit increased resistance to the deleterious effects of ionizing radiation. We determined whether suppressing
p53 expression by antisense MOs similarly induced a radioresistant phenotype. We observed that p53-targeted MO kd markedly improved survival of zebrafish embryos irradiated with 20 Gy at 24 hpf (Fig. 1A) whereas coinjection of capped p53 mRNA restored radiation sensitivity (Fig. 1B). Similarly, p53-targeted MO kd markedly reduced the incidence and severity of radiation-induced morphological defects, notably defects in midline development that manifest as dorsal curvature of the body axis (Fig. 5). These results were similar to results by Duffy and Wickstrom published during preparation of this manuscript.25 In addition, p53-targeted MO kd markedly reduced the extent of radiation-induced apoptosis as determined by acridine orange staining (Fig. 1C).

Effects of the pharmacological p33 inhibitor PFTα on development and radiation sensitivity of zebrafish embryos. PFTα was originally identified as an inhibitor of p33-dependent transcription26 and it reduced the sensitivity of mice to the deleterious effects of ionizing radiation.27 Based on these previous studies we tested whether PFTα also protected zebrafish embryos against radiation-associated toxicity (Fig. 2A). Unexpectedly, when added to zebrafish embryos at 3 hpf (sphere stage), PFTα (2 μM) caused malformations affecting the head region and led to the development of massive edema affecting the whole body of treated fish at later stages of development (Fig. 2B and Table 1). Furthermore, it has been described earlier that PFTα treatment also reduces overall survival of zebrafish embryos.28 These results together raised the question whether PFTα exerted effects on molecular targets other than p53, which could confound potential radioprotective properties of PFTα in the zebrafish embryo.

PFTα treatment mimics morphological effects associated with knockdown of p73 expression in zebrafish embryos. P73 is a likely candidate for off-target effects of PFTα because p73 binds to and transactivates p53 responsive promoters.29 Thus, we determined whether suppression of p73 expression by antisense MO kd caused developmental defects similar to those observed in PFTα treated embryos. A previous report showed that targeting p73 adversely affected development of the head region, i.e., the olfactory system, the telencephalon and the pharyngeal arches of zebrafish embryos.26 In addition, p73 is expressed at high levels in the developing kidneys.28 We observed that p73-targeted antisense MO kd induced head region abnormalities (Fig. 3A) and led to liquid accumulation affecting the whole body of treated fish (Fig. 4 and Table 1). These changes were very similar to the morphological alterations observed in PFTα-treated fish (Fig. 2B). Furthermore, alizarin blue staining revealed severe disturbances of branchial arch development associated with either PFTα treatment or p73-targeted antisense MO kd (Fig. 3B). These defects were, at least partially, reversed by coinjection of G-capped p53 MO and not observed in embryos injected with p53 mismatch antisense MO.26

Impaired kidney function in zebrafish treated with PFTα and p73 morpholinos. This is the first report of edema formation upon treatment of developing embryos with p73-targeted antisense MO kd. We hypothesized that this phenotype was due to impaired renal clearance consistent with high-level expression of p73 in the developing kidneys.30 To address this issue we used a renal function assay, which measures retention of a fluorescent dextran within 24 h after injection into the cardiac venous sinus.26 As compared to control fish receiving mismatch antisense MO, the p73-targeted antisense MO kd caused markedly reduced clearance of this contrast agent (Fig. 5). In contrast, control p53-specific antisense MO kd did not affect dextran retention. Importantly, PFTα treatment not only led to liquid accumulation in fish embryos in a manner similar to p73-targeted antisense MO kd but it also increased dextran retention in

Figure 1. Antisense morpholino oligonucleotides (MOs) targeted to p53 increase embryo survival and reduce ionizing radiation-induced apoptosis evident in the head and trunk regions. (A) Embryo survival. Triplicate dishes of 60 embryos each were scored for live embryos daily after 20 Gy IR administered at 24 hpf. Necrotic dissolution or absent heartbeat were considered criteria for embryo death. (B) Iodination of IR sensitivity by coinjection of capped zebrafish p53 mRNA. Triplicate dishes of 60 embryos each were scored as described above at 6 dpf (Days post IR). Asterisks (*) p53 kd vs p53 kd-p53 mRNA, p < 0.05; t-test, one-tailed). (C) Attenuation of IR-induced apoptosis by p53 kd as assayed by quantification of acridine orange staining at 30 hpf (1 day post IR). Control, p53 kd, p53 kd-p53 mRNA, mismatch antisense MO-kd p53 kd, p53 antisense MO-p53 kd-p53 mRNA, rescue coinjection with p53 antisense MO and p53 G-capped mRNA were pooled and stained with AO as described in Materials and Methods. Pooled embryos were transferred to 95% ethanol for 15 minutes to extract the AO for fluorescence determination. Triplicate measurements for each condition were performed on a Tecan microplate fluorescence reader (Bio-Tek) and normalized to control background fluorescence and reported as relative fluorescence units (RFU).

either PFTα treatment or Quantitative analysis of the images revealed only marginal effects of microscopy of cardiac contractility in control and irradiated fish embryos. The striking similarities in developmental sive promoter construct. PFTα inhibits p73-dependent transactivation of a p53-respon-
due primarily to compromised renal function. 

An alternative explanation for the profound edema in zebrafish embryos following IR exposure is that this effect was caused by reduced cardiac function.28 To investigate this possibility, we performed time-lapse microscopy of cardiac contractility in control and irradiated fish embryos. Quantitative analysis of the images revealed only marginal effects of either PFTα treatment or p73-specific antisense MO kd on heart rate and blood flow (not shown). Collectively, these results suggest that the edema observed in PFTα and p73 antisense MO kd zebrafish embryos is due primarily to compromised renal function.

PFTα inhibits p73-dependent transcription of a p53-respon-
sive promoter construct. The striking similarities in developmental abnormalities caused by either PFTα treatment of suppression of p73 expression raised the question whether PFTα targeted not only p53-
dependent but also p73-dependent transcription. Using a p53 responsive reporter gene construct and zebrafish p53 and p73 expression plasmids co- transduced into Saos-2 cells we observed that PFTα not only inhibited p53-dependent transcription but also p73-dependent transcription in a dose-dependent manner (Fig. 6).

It should be noted that administration of PFTα shortly before radiation (i.e., at 21 hpf ) did not cause developmental abnormalities either of the craniofacial region or systemic edema and provided a measure of protec-
tion against radiation similar to that observed in p53 antisense MO kd fab (Fig. 5). This result indicates that p73 serves essential functions during the first 24 h of zebrafish development but is less relevant at later developmental stages and, presumably, in the adult organism. This cir-
cumstance also explains why inhibition of p73 function by PFTα has not been obvious in previous in vitro or in vivo studies in adult mice. In summary, this report demonstrates the utility of the zebrafish model system in characterizing drug effects and highlights previously unrecognized effects of the p53 inhibitor PFTα related to inhibition of p73 function. Lack of either p53 or p73 function is associated with chemoresistance of transformed cells.29 Furthermore, p73 is induced after DNA damage by the checkpoint kinases Chk1 and Chk2.25 Based on these results, p73 has been considered as the “assistant” guardian of the genome that acts in concert with p53 to limit propagation of cells with damaged DNA.31 Since we observed that PFTα inhibits not only p53-dependent but also p73-dependent transcription the overall radio protective effect of PFTα as observed in mice may, thus, be due to inhibition of p53 and p73 function. Indeed, short-term pharmacological inhibition of both, p53 and p73 may be superior to inhibition of p53 alone to protect normal adult cells and tissues against deleterious effects of radiation.

Materials and Methods

Embryo harvesting and maintenance. Zebrafish husbandry, embryo collection, dechorionation and embryo maintenance were performed according to accepted standard operating procedures32 and with approval by the Institutional Animal Care and Use Committee at Thomas Jefferson University. Zebrafish were maintained in the Zebrafish Core Facility of the Kimmel Cancer Center at Thomas Jefferson University at 28.5°C on a 14-h light/10-h dark cycle.

Zebrafish morphology by visual analysis. For visual analysis, zebrafish embryos were anesthetized with 0.003% tricaine, placed on 3% meth-
ycellulose on a glass depression slide and analyzed using an Olympus BX51 microscope (Olympus, Melville, NY) at 4x magnification. Images were recorded using a SPOT camera and SPOT Advanced software (SPOT Diagnostic Instruments, Sterling Heights, MI).

Targeted knock down of gene expression. Antisense MO sequences targeting p53, p73 and controls (5 base mismatches; p53 mm, p73 mm) were as described.4,40 For microinjection, a 0.5 mM oligonucleotide solu-
tion was prepared in 10x phosphate-buffered saline solution, diluted 9:1

Figure 2. PFTα (2 μM) administered to zebrafish embryos at 3 hpf does not protect against the lethal effects of IR and is associated with developmental abnormalities. (A) Embryos screened as described in Figure 1A (B) Embryos morphology in the different experimental conditions as indicated. Representative embryos were digitally photographed at 4x magnification and processed using NIH ImageJ software.
with Phenol Red dye, and ~1 nL injected into 1–4 cell embryos using a nitrogen gas pressure injector (Harvard Apparatus, Cambridge, MA). To account for non-specific effects of MO oligonucleotides, rescue experiments were carried out by coinjection of MOs with G-capped mRNA of the respective target gene. To this end, triplicate dishes of 60 embryos were injected with 4.5–7.5 pg of mRNA generated by cloning the zebrafish \( p53 \) or \( p73 \) cDNA into the pCS2+ vector and producing mRNA with the mMessage-mMachine SP6 kit (Ambion, Austin, TX).

Radiation exposure and PFTα protection. Triplicate dishes (60 embryos each) were irradiated at 24 hpf (20 Gy) using 250 kVp X-rays (PanTak, East Haven, CT) at 50 cm source-to-skin with a 2-mm aluminum filter. Dose-metric calibration was performed before each experiment using a thimble ionization chamber (Victoreen; Elimpex-Medizintechnik, Moedling, Austria) with daily temperature and pressure correction. Pifithrin-α (EMD Biosciences, San Diego, CA) was solubilized in DMSO and diluted with embryo media. PFTα was applied 30 minutes prior to IR.

Kidney function assay. A 1% solution of rhodamine-labeled dextran (10 kDa; Molecular Probes) in PBS was injected (3 dpf) using glass micropipets into the cardiac venous sinus of embryos immobilized in 3% methylcellulose. Prior to injection, embryos were anesthetized using a 0.003% tricaine solution in egg water.33 After injection, the embryos were washed in egg water for 10 minutes and placed back into 3% methylcellulose on a glass depression slide. Fluorescence was quantitated using ImageJ software (NIH, USA). The analysis was repeated at 24 h after dextran injection. Percent dextran retention at 24 h was calculated using the formula: \( \text{Percent dextran retention} = \left( \frac{\text{intensity 24 h}}{\text{intensity 0 h}} \right) \times 100 \).

Cartilage shows markedly abnormal cranio-facial development associated with PFT-α treatment and with p53 antisense MO kd.

![Figure 4](image_url) (Figure 4). Phenotypic abnormalities associated with PFT-α treatment are similar to those caused by MO-mediated p73 kd. Embryo morphology and rescue by G-capped mRNA. Representative embryos were digitally photographed at 6x magnification and processed using NIH ImageJ software.

![Table 2](image_url) (Table 2). Incidence of whole body edema caused by p73kd.

1. (v) with Phenol Red dye, and ~1 nl injected into 1–4 cell embryos using a nitrogen gas pressure injector (Harvard Apparatus, Cambridge, MA). To account for non-specific effects of MO oligonucleotides, rescue experiments were carried out by coinjection of MOs with G-capped mRNA of the respective target gene. To this end, triplicate dishes of 60 embryos were injected with 4.5–7.5 pg of mRNA generated by cloning the zebrafish \( p53 \) or \( p73 \) cDNA into the pCS2+ vector and producing mRNA with the mMessage-mMachine SP6 kit (Ambion, Austin, TX).
Alcian blue staining. Alcian blue staining was performed according to Neuhaus et al., with the following modifications. Embryos (4 dpf) were fixed overnight in Davidson’s Solution (Electron Microscopy Sciences, Hatfield, PA) and rinsed 3x for 10 min in PBS and transferred to neutral buffered formalin for 2 days at 4°C. The embryos were then transferred into distilled water and stored at 4°C. For Alcian blue staining, the samples were washed in PBT (0.1% Tween-20 in PBS) and transferred into 30% H2O2 (Sigma, St. Louis, MO) and bleached for 4–5 hours or until eyes became translucent. After bleaching, the embryos were rinsed in PBS for 15 min and transferred to filtered Alcian Blue solution (1% conc HCl, 70% Ethanol, 0.1% Tween-20) and stained overnight. The stain was cleared with acidic ethanol (5% conc HCl, 70% ethanol).

Acridine orange staining. Zebrafish embryos were dechorionated and placed in 50 μg/ml of acridine orange (Sigma) in fish water. After 30 min of staining, embryos were washed 3x for 10 min in PBS. Pooled embryos were transferred to 95% ethanol for 15 minutes to extract the AO for fluorescence determination. Triplicate measurements for each condition were performed on a FL600 microplate fluorescence reader (Bio-Tek) and normalized to control background fluorescence and reported as relative fluorescence units (RFU).

In vitro reporter gene assays. Saos-2 cells (ATCC Rockville, MD) were cultured in DMEM supplemented with 10% fetal calf serum. Cells were cultured to 60–70% confluence and transfected to 48-well plates at a density of 2.6 x 10^4 cells/well. Cells were transfected with three plasmids.
using Fugene (Roche). The p53 reporter plasmid was constructed by inserting the synthetic p53-responsive promoter containing 14 tandem p53 enhancer elements and a TATA-box (Pathoject p53-50 reporter, Stratagene) into the pGL3-null plasmid (Promega) to drive the Renilla luciferase gene (p53-Pr-50). For normalization, a B-galactosidase activity was measured 48 hrs after transfection using the Dual-Luciferase Reporter Assay System (Promega, Madison, WI) and B-gal activity was measured using the Beta-Glo Reporter Assay System (Promega, Madison, WI) according to the manufacturer’s specifications. Cells were treated with PFA for 15 minutes before transfection. Chemiluminescence was measured using a Ventana Microluminescet (Ventana Biosystems, Sunnyvale, CA).
